Part of the Nursing Commons

The College of Nursing showcases some of our best evidence based scholarly papers from graduate students in the Family Nurse Practitioner Program. The papers address relevant clinical problems for advance practice nurses and are based on the best evidence available. Using a systematic approach students critically analyze and synthesize the research studies to determine the strength of the evidence regarding the clinical problem. Based on the findings, recommendations are made for clinical practice. The papers are published in professional journals and presented at professional meetings.

ABSTRACT

Vitamin B₁₂: Identification and Treatment of Deficiencies

Max E. Mitchell
College of Nursing
Master of Science

Vitamin B₁₂ is essential for the proper functioning of all cells. A deficiency can cause serious hematologic and neurologic damage. Groups at high risk for developing vitamin B₁₂ deficiency include the elderly, vegetarians, pregnant women, persons with pernicious anemia, and patients with a history of gastrointestinal (GI) surgery. The purpose of this article is to increase awareness of vitamin B₁₂ deficiency and discuss its pathophysiology, symptoms, diagnostic testing, and management.

Keywords: Vitamin B₁₂, cobalamin, deficiency, risk factors, symptoms, management
ACKNOWLEDGMENTS

I would like to express gratitude to Dr. Donna Freeborn for her support, guidance, understanding, and encouragement throughout the writing process. She has been generous with her time and helped me meet the necessary deadlines. Her knowledge as an FNP has been invaluable.

I would also like to thank Dr. Renea Beckstrand who oversaw this paper in its beginning stages and provided direction for research, outline, and writing techniques.

Dr. Beth Luthy also provided many insightful comments and suggestions. Her fresh perspective and knowledge of how to increase this paper's potential for publication were greatly appreciated.

Thank you to my wife, Lana, for her patience, unconditional love, and support.

And finally, to Maddie, Max, Will, and Josh: Thank you for being the best kids I could ask for.

Vitamin B₁₂: Identification and Treatment of Deficiencies

Vitamin B₁₂, also known as cobalamin, is a water-soluble vitamin containing cobalt, a compound essential for maintaining the health of all cells because it is needed for production of DNA and RNA, the body’s genetic material.¹ Vitamin B₁₂ is especially important in maintaining the health of the body’s nerve and blood cells.²-⁴ Specifically, it is crucial for maintaining healthy nerve cells⁴ and supporting bone marrow production of red blood cells (RBCs).²

Deficiency of vitamin B₁₂ can lead to serious complications in hematologic and neurologic systems.⁵,⁶ Causes of deficiency include inadequate intake, absorption, and transport.² Recognizing a deficiency and providing prompt treatment is essential to preventing severe hematologic issues and possibly irreversible neurologic damage due to demyelination.⁵-⁷

Vitamin B₁₂ deficiency is a disorder that affects a significant number of adults, particularly those in high-risk groups. In fact, it is estimated that 3% to 40% of the general population is deficient in vitamin B₁₂ (depending on the diagnostic criteria used), and an additional 15% over the age of 60 are believed to be undiagnosed.²,⁸,⁹ Although vitamin B₁₂ deficiency can affect persons of all ages, the incidence of deficiency increases with age.⁵,⁶ Other groups at high risk for vitamin B₁₂ deficiency include vegetarians, pregnant women, those with pernicious anemia, and patients with a history of gastrointestinal (GI) surgery.¹,²,³,¹⁰ Strict vegans are at particular risk for developing a vitamin B₁₂ deficiency and are 10 times more likely than vegetarians, and 50 times more likely than the general population, to develop a deficiency.¹

As primary care providers, Nurse Practitioners (NPs) treat patients across the lifespan and should be aware of vitamin B₁₂ deficiency as a potential diagnosis in high-risk groups of all ages. The purpose of this article is to provide NPs with an overview of the importance of vitamin B₁₂,
how to identify those at risk and recognize a deficiency, and to provide a guideline for treatment management and education for patients with this condition.

VITAMIN B₁₂ DEFICIENCY

Pathophysiology

To understand vitamin B₁₂ deficiency, it is helpful to first understand the basic process by which vitamin B₁₂ (cobalamin) is utilized in the body. Once ingested, cobalamin is released from the food complex by pepsin and hydrochloric acid in the stomach.⁵ The free cobalamin binds to a glycoprotein in saliva (gastric R binder), and the complex moves into the duodenum and jejunum where pancreatic enzymes break down the complex and release cobalamin.¹¹ Cobalamin then binds to intrinsic factor, which is secreted from the parietal cells of the stomach.⁶,¹¹ Once bound with intrinsic factor, the compound becomes Cobalamin-Intrinsic Factor (CIF) complex, which is then absorbed in the distal ileum, releasing cobalamin into the plasma.⁶,¹¹ There must be sufficient dietary intake of vitamin B₁₂, acid-pepsin in the stomach, pancreatic proteases, functional intrinsic factor, functioning CIF receptors in the ileum, and an intact upper GI tract for adequate absorption to occur.⁶ A disorder in any of these areas can result in vitamin B₁₂ deficiency.⁵,⁶,¹¹

Risk Factors

Although vitamin B₁₂ deficiency can occur among the general population, it is important for NPs to be aware of high-risk groups to avoid a delay in diagnosis and treatment. Although traditionally considered a disorder of the elderly, research has shown that vegetarians and vegans, pregnant women, those with pernicious anemia, and individuals with a history of GI surgery are also at an increased risk for a deficiency.³,¹² It is important, therefore, not only to recognize these individuals but to understand how different risk factors contribute to a vitamin
B_{12} deficiency. This understanding is essential when developing a management plan appropriate for the individual.

**Older Adults.** Vitamin B_{12} deficiency occurs frequently in older adults, especially those in their 70s and 80s, and is usually due to malabsorption of food-bound vitamin B_{12}.^{2,8,13} As individuals age, atrophic gastritis and bacterial overgrowth of the GI tract can either individually or in combination cause reduced gastric acid production, resulting in malabsorption of food-bound vitamin B_{12}.^{8} Hvas suggests age-related gastric atrophy also contributes to malabsorption.^{12} Chronic atrophic gastritis, which affects as many as 30% of older adults, is a condition that results in the degeneration and thinning of the stomach wall, leading to gastric cell atrophy and a decrease in the production of stomach acids, thus minimizing the body’s ability to absorb vitamin B_{12}.^{2,3,13} Therefore, elderly individuals with a vitamin B_{12} deficiency might not be able to adequately absorb oral vitamin B_{12} replacements. This should be considered when discussing treatment options.

**Vegetarians.** Vegetarians and vegans are at high risk for developing a vitamin B_{12} deficiency because they do not ingest foods of animal origin, such as meat and dairy products, which contain vitamin B_{12}. It was once thought that only strict vegans lacked adequate intake of vitamin B_{12} containing foods, however, it is now known that deficiencies can be found among persons observing all types of vegetarian diets, including lacto-ovo-vegetarians.^{14} Although vegetarians and vegans might vary in their consumption of the types of foods that contain vitamin B_{12}, a vegetarian or vegan diet that does not allow for adequate amounts of vitamin B_{12} will influence their management plan.

**Pregnancy.** Vitamin B_{12} is essential for cell multiplication during pregnancy because of its important role in DNA synthesis.^{10} Although pregnancy itself does not cause a deficiency,
pregnant women with low vitamin B$_{12}$ levels might be at higher risk for giving birth to a baby with adverse fetal and neonatal outcomes, primarily neural tube defects.$^{10}$ Pregnant women have the same risk for vitamin B$_{12}$ deficiency as the general population, or might be at greater risk due to dietary restrictions. However, identifying women at risk or with a deficiency prior to pregnancy is crucial to ensure that essential DNA synthesis can occur and to prevent or minimize adverse fetal outcomes.$^{10}$

**Pernicious Anemia.** Patients with pernicious anemia are at high risk for developing a vitamin B$_{12}$ deficiency.$^{7}$ Pernicious anemia is an autoimmune condition resulting from the destruction of gastric parietal cells and the associated lack of intrinsic factor needed to bind ingested vitamin B$_{12}$. Without intrinsic factor, vitamin B$_{12}$ absorption is limited to a very small amount through passive diffusion. The absence of intrinsic factor might be congenital or a developed condition, as seen in atrophic gastritis.$^{2}$ Those at risk for pernicious anemia are adults aged 50 to 60 years, women, and those of African or European descent.$^{2,7}$ The inability of individuals with pernicious anemia to absorb vitamin B$_{12}$ from food will also influence their management plan.

**Gastrointestinal Surgery.** Individuals who have undergone some types of gastrointestinal surgery are at greater risk for a vitamin B$_{12}$ deficiency as a result of the surgery.$^{2}$ A total gastrectomy leads to a loss of cells that secrete pepsin or intrinsic factor and hydrochloric acid, resulting in an inability to absorb vitamin B$_{12}$. Partial gastrectomy also causes decreased vitamin absorption because it leads to the development of atrophic gastritis.$^{2,3}$ Just as in the elderly who develop atrophic gastritis, partial gastrectomy patients develop gastric cell atrophy and a decrease in the production of stomach acids, minimizing the body’s ability to absorb vitamin
When developing a treatment plan for patients with a history of GI surgery, their inability to absorb vitamin B₁₂ from food should be considered.

**Presentation**

Patients with a vitamin B₁₂ deficiency might be asymptomatic or present with symptoms that range from mild to severe. Symptoms usually develop over several years and are often vague.²⁻⁴,⁶ It is important that NPs include vitamin B₁₂ deficiency as part of their differential diagnosis when patients present with any of the following symptoms (Table 1).

**Table 1.**

<table>
<thead>
<tr>
<th>Common Symptoms of Vitamin B₁₂ Deficiency</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Eyes:</strong> Loss of central vision; pale conjunctiva</td>
</tr>
<tr>
<td><strong>Oral:</strong> Enlarged inflamed tongue; mucosal ulceration(s)</td>
</tr>
<tr>
<td><strong>Skin:</strong> Jaundice; pigment changes</td>
</tr>
<tr>
<td><strong>GI:</strong> Loss of appetite; digestive issues</td>
</tr>
<tr>
<td><strong>Hematologic:</strong> Anemia</td>
</tr>
<tr>
<td><strong>Neurological:</strong> Impaired gait and balance; peripheral paresthesia and numbness to hands and feet; generalized weakness; loss of position and vibratory sense; dizziness</td>
</tr>
<tr>
<td><strong>Cognitive:</strong> Impaired memory and concentration</td>
</tr>
<tr>
<td><strong>Behavioral:</strong> Anxiety; depression</td>
</tr>
</tbody>
</table>

**Physical Examination**

There are no classic clinical manifestations or "gold standard" available to assist in making a diagnosis of vitamin B₁₂ deficiency. In fact, symptoms might be attributed to other
diagnoses. A thorough history can help the NP identify risk factors and develop appropriate differential diagnoses, thus focusing the physical examination. For instance, when examining an elderly patient, the NP should watch for even the smallest signs of neurologic or cognitive dysfunction, which might otherwise be attributed to early signs of dementia. In other words, when a patient in a risk group for a vitamin B\textsubscript{12} deficiency presents with symptoms consistent with a deficiency, the NP should focus the physical examination on other signs of deficiency including jaundice, oral manifestations, or neurological changes as outlined in Table 1. Early suspicion of vitamin B\textsubscript{12} deficiency can lead to early diagnosis and treatment, eliminating the development of potentially serious neurological and hematological complications.

**Diagnostic Testing**

Patients who belong to high-risk groups, or those with signs and symptoms consistent with a vitamin B\textsubscript{12} deficiency, should be evaluated. A serum cobalamin (B\textsubscript{12}) level and a complete blood count (CBC) to identify the presence of any type of anemia are recommended for initial testing. Vitamin B\textsubscript{12} concentrations are generally accurate; however, these tests screen for a deficiency only and will not determine the actual cause. Additionally, not all patients with a deficiency will have hematological manifestations. There are instances where falsely low serum B\textsubscript{12} levels have been associated with the use of oral contraceptives, folate deficiency, and pregnancy. Falsely high serum B\textsubscript{12} levels might be associated with conditions such as liver disease, renal disease, or myeloproliferative disorders. There are conflicting guidelines for determining a deficiency in cobalamin levels, but generally patients with levels less than 200 pg/mL are considered deficient. Symptomatic patients with levels between 200 and 300 pg/mL might be deficient and supplementation could be beneficial. Symptomatic patients with levels higher than 300 pg/mL are most likely not vitamin B\textsubscript{12}
deficient. If the vitamin B₁₂ level is normal but your patient's symptoms are consistent with a deficiency, it is appropriate to follow up with methylmalonic acid (MMA) and homocysteine levels. These tests might be more sensitive to identifying a vitamin B₁₂ deficiency, especially in elderly patients.⁶,¹⁶,¹⁷

**Management**

**Supplementation.** Vitamin B₁₂ supplements are available in several forms: injectable, oral, sublingual, and intranasal.¹⁸ Treatment is determined by the cause of the deficiency, patient preference, and cost.²,⁶ Traditional treatment for vitamin B₁₂ deficiency is intramuscular (IM) administration of cyanocobalamin, a synthetic form of vitamin B₁₂.¹,⁴,¹⁹ Cyanocobalamin therapy is usually initiated by administering 1,000 mcg IM every day for 1 or 2 weeks, followed by 1,000 mcg IM every week for 4–6 weeks. Afterward, a maintenance dose of 1,000 mcg IM every month will be needed.⁵

For patients who prefer a different route, high-dose oral treatment is also effective and is increasingly popular.⁷ An oral dose of 1,000 to 2,000 mcg per day is usually sufficient.²⁰ For patients who are unable to actively absorb vitamin B₁₂ (pernicious anemia), passive absorption in the small bowel still allows an absorption rate of 1%. Therefore, supplementation with 1,000 mcg per day can provide 10 mcg, substantially more than the Recommended Dietary Allowance (RDA) of 2.4 mcg per day.²,²⁰ When absorption is a concern, IM is the suggested route of treatment due to its higher absorption rate.¹,⁶ Toxicity risk from dietary vitamin B₁₂ is unlikely.¹,³,²⁰ Patients with a deficiency who are prescribed very high doses of vitamin B₁₂ have shown no signs of toxicity.¹,¹⁷ It is impossible to consume too much in your diet and any excess is excreted in the urine.¹,¹⁷ Patients often choose oral treatment to avoid pain from injections, the
inconvenience of an office visit, and cost.\textsuperscript{21,22} The overall goal of supplementation is to determine the level of deficiency and adequately replace vitamin B\textsubscript{12} levels.

\textit{Dietary.} Vitamin B\textsubscript{12} is found mostly in foods of animal origin such as meat and dairy products, including liver, beef, chicken, pork, eggs, milk, cheese,\textsuperscript{15} and some varieties of fish.\textsuperscript{8} Many breakfast cereals are also fortified with up to 100\% of the daily value of vitamin B\textsubscript{12}. The RDA was set at 2.4 µg/d by the Institute of Medicine (IOM) to ensure absorption of 1 µg/d because on average only about 50\% of vitamin B\textsubscript{12} is absorbed from food.\textsuperscript{7} The RDA for vitamin B\textsubscript{12} in pregnancy is 2.6 µg/day, which is 0.2 µg/day greater than the RDA for non-pregnant women and adolescents. A balanced diet, however, provides somewhere between 7 and 30 µg/day.\textsuperscript{3}

Many older adults have difficulty absorbing vitamin B\textsubscript{12}; therefore, the IOM recommends all adults over 50 include B\textsubscript{12}-fortified foods or B\textsubscript{12} supplements in their diet.\textsuperscript{1,3,23} Vegans and strict vegetarians, especially those who are pregnant or breastfeeding,\textsuperscript{3,11} are also encouraged to consume B\textsubscript{12}-fortified foods such as breakfast cereals, soy milk, and certain soy analog meats,\textsuperscript{14} or include supplements in their diets.

Vitamin B\textsubscript{12} has the potential to interact with alcohol and certain medications such as chloramphenicol and colchicines because they affect the way the body breaks down nutrients. Other medications including oral contraceptives, potassium supplements, Metformin, antivirals, and nicotine interfere with the absorption of vitamin B\textsubscript{12}.\textsuperscript{3,18,24} Long-term use of proton pump inhibitors (PPIs) are known to reduce vitamin B\textsubscript{12} levels obtained from food but not from supplements; therefore, B\textsubscript{12} levels should be tested because supplementation could be necessary.\textsuperscript{18} Early education of patients who use PPIs regarding the potential of a B\textsubscript{12} deficiency can avoid the possibility of an interaction.
**Patient Education.** Patient and family education should include information regarding vitamin B₁₂ deficiency, common symptoms, dietary needs, supplementation (including associated costs), and the possible need for lifelong vitamin B₁₂ replacement.²,⁶ Patients could be taught to self-administer cyanocobalamin by injection (if needed), giving them a sense of control and the ability to manage their disorder.⁵,⁶ Patients might also be made aware of available resources that provide helpful information about vitamin B₁₂ deficiency, including online medical sources and pamphlets. A referral to a dietitian and regular office visits will also assist with proper management and compliance.⁶,⁹

Dietitians can be helpful for providing guidance to patients with a deficiency on how to increase their vitamin B₁₂ intake. Patients in each of the high risk groups have unique dietary needs. Working with a dietician can assist a patient in creating a personalized dietary plan to meet individual needs and tastes while boosting vitamin B₁₂ levels.⁶

**Conclusion**

Vitamin B₁₂ deficiency is more common than NPs might realize. It is important to be aware of this condition as a potential diagnosis for the elderly and for patients from high-risk groups. Understanding its pathophysiology, recognizing symptoms, and providing treatment are foundational to early detection, thereby avoiding the potential devastating consequences of untreated vitamin B₁₂ deficiency.
