Brigham Young University, Provo, Utah

Members of the Editorial Board:
Vernon J. Tipton, Zoology
Ferron L. Anderson, Zoology
J. V. Beck, Microbiology
Joseph R. Murdock, Botany
Wilmer W. Tanner, Chairman of the Board

Ex officio Members:
A. Lester Allen, Dean, College of Biological and Agricultural Sciences
Ernest L. Olson, Chairman, University Publications

The Brigham Young University Science Bulletin, Biological Series, publishes acceptable papers, particularly large manuscripts, on all phases of biology.

Separate numbers and back volumes can be purchased from University Press, Brigham Young University, Provo, Utah. All remittances should be made payable to Brigham Young University.

Orders and materials for library exchange should be directed to the Division of Gifts and Exchange, Brigham Young University Library, Provo, Utah 84601.

NEW RECORDS AND SPECIES OF NEOTROPICAL BARK BEETLES (SCOLYTIDAE: COLEOPTERA) PART IV

By
Stephen L. Wood

On the following pages 108 species and two subspecies of bark beetles (Scolytidae) are described as new to science. It was intended that most of these would be named in a synopsis of the Scolytidae of Costa Rica; however, the volume of undescribed material proved to be so large and the manuscript treating it so bulky that its completion became impractical. That manuscript, with its keys, host and geographical distributions, and biological notes is being expanded into a treatment of the entire American continent north of Panama. In order to stabilize new names for that project, they are validated below.

The new species represent the following genera: Xylechius (1), Phrixosoma (1), Phloeosinus (1), Chramesis (8), Phloeotribus (5), Chaeophloeus (1), Liparitrum (2), Gnemonyx (5), Camptocerus (1), Scolytus (2), Microborus (2), Scolytoles (22 with 2 subspecies), Pseudothyasanae (16), Cryptulocephus (13), Thysanae (4), Microacisella (8), Micravis (9), Hlycurus (4), Phloeoleptus (3). They are from the following countries: Mexico (49), Guatemala (9), Honduras (7), Costa Rica (49), Panama (5); seven species occurred in two countries, and two species occurred in three countries.

Except as noted below, all type series were tentatively deposited in my personal collection presently housed at the Brigham Young University, in order to facilitate preparation of a monograph of the Scolytidae of the western hemisphere. Upon conclusion of that monograph, paratypes will be distributed, in so far as possible, to at least two European and two other American collections. The British Museum (Natural History) has already received paratypes of many species.

Xylechius avarus, n. sp.
The large body size, the stout form, the elevated declivital interspaces 1 and 3 on the elytra, the fine ground vestiture, and the fine, low frontal carina serve to distinguish this species. Of the species known to me it is perhaps more closely allied to fuliginosus Blandford, although the relationship is remote.

Female.—Length 3.2 mm. (paratypes 2.4-3.3 mm.), 2.1 times as long as wide; body color brown, usually covered by an incrustation.

Frons convex, with a feeble transverse impression just below upper level of eyes, a low acutely elevated median carina extending from this impression to epistomal margin; entire surface coarsely reticulate, punctures fine, inconspicuous; vestiture short sparse inconspicuous.

Pronotum 0.93 times as long as wide; sides widest and almost parallel on middle half, strongly constricted one-fourth length from anterior margin, rather broadly rounded in front; surface finely granulate and with rather sparse, round, small vulcanate punctures; vestiture consisting of short, rather stout, moderately abundant bristles.

Elytra 1.2 times as long as wide, 1.8 times as long as pronotum; sides almost straight, very slightly wider at declivital base, narrowly rounded behind; striae impressed, the punctures deeply, not sharply impressed; intersstriae about one and one-half times as wide as striae, irregular, the punctures fine, abundant, confused, with a median row of larger, granulate punctures, crenulate toward base. Declivity convex, rather steep; striae impressed; interspace 2 impressed, strongly narrowed, ending before apex, 1, 3, and 9 elevated, about half as high as wide, 3 and 9 join apically, the elevation continued to 1, granules not as large as on disc. Vestiture of short, rather abundant, stout, hair-like setae, and interspacial rows of long bristles, spacing between bristles and between rows equal to length of a bristle.

Male.—Similar to female except frons flattened on lower half; and ground vestiture evidently more abundant.

Type Locality.—Volcan Irazu, Cartago Prov., Costa Rica.

Host.—Oreopanax nubigenus.

Type Material.—The male holotype, female allotype, and 205 paratypes were collected at the type locality on October 26, 1963, at an elevation of 2,300 m., by S. L. Wood, from the fallen epiphytic host that was about 10 cm. in diameter. The galleries were similar to those of fuliginosus. The holotype, allotype and paratype are in my collection.

Phrixosoma clusiae, n. sp.
This species is very closely related to minor Wood, but it may be distinguished by the larger size, by the much more strongly impressed female vertex, by having the interstitial granules three-ranked almost to elytral base, by the comparatively wider discal interstriae, and by the less definitely granulate anterior slope of the pronotum.

Female.—Length 2.5 mm. (paratypes 1.9-2.5 mm.), 1.9 times as long as wide; color black.

Frons broadly convex from epistomal margin to upper level of eyes; rather strongly, transversely, acutely impressed from just above level of eyes to vertex, upper margin of this groove abruptly angled; lateral angles of groove produced laterally causing a pro-

1 Part of the field work that led to the discovery of these insects was sponsored by the National Science Foundation.

2 Department of Zoology and Entomology, Brigham Young University, Provo, Utah. Scelothoides contribution number 38.
nounced situation in line where pubescent and non-pubescent areas meet; vestiture hairlike, short, rather abundant, extending to vertex.

Pronotum 0.90 times as long as wide; widest at base, sides uniformly, convolutely arcuate to weak constriction just before the rather narrowly rounded anterior margin; anterior third very minutely asperate, asperities on margin somewhat larger; surface rather closely marked by low, subtuberculate, short, irregular rugae (remnants of interspaces between obsolete punctures), depressed areas reticulate; vestiture consisting of very fine, short hair.

Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; outline as in obesa; narrowly impressed, the punctures small, distinct; interstriae almost three times as wide as striae, reticulate, granules rather large, rounded, three-ranked almost to base except on 2, the marginal rows of granules becoming smaller by middle of disc and obsolete by upper fourth of declivity. Declivity and vestiture as in minor.

Male.—Similar to female except frontal carina absent, vertex and anterior margin of pronotum not modified, and asperities on anterior third of pronotum almost obsolete.

Type Locality.—Lamorano, Morazan, Honduras.

Host.—Clusia flavia.

Type Material.—The female holotype, male allotype, and ten paratypes were collected at the type locality on April 18, 1961, 700 m. elevation. No. 561, in branches and bole of Clusia flavia. This monogamous species constructs biramous, transverse egg galleries in the cambium region essentially as in minor.

The holotype, allotype, and paratypes are in my collection.

_Phracocinus palearis_, n. sp.

This species is closely allied to _serriatus_ LeConte, but it may be distinguished by the smaller size, by the numerous minute points and/or fine lines in the interspaces between punctures on the pronotal disc, by the less numerous, smaller submarginal crenulations at the elytral bases, and by the less strongly compressed teeth on the male elytra declivity, the anterior profile of each tooth usually evenly arcuate (abruptly angled in _serriatus_).

Male.—Length 2.4 mm. (paratypes 1.9–2.5 mm.), 1.95 times as long as wide; color very dark brown.

Elytra feebly convex, almost flat, the lower fourth gradually ascending to epistomial margin; lower half marked by a fine, low median carina; surface smooth with rather fine, deep, close punctures, some subgranulate in area median to upper half of eye; vestiture fine, moderately long, rather abundant. Vestiture on anterior club short, more abundant than in allied species.

Pronotum 0.82 times as long as wide; widest near base, sides uniformly, convolutely arcuate to moderate constriction just before broadly rounded anterior margin; surface smooth, with some minute points and lines in interspaces between the moderately large deep punctures; interspaces one-fourth to equal in width to diameter of a puncture. Vestiture fine, rather short, moderately abundant.

Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; basal margins armed by 12 crenulations on interstriae 2; striae narrowly impressed, the small punctures somewhat obscurely indicated; interstriae about three times as wide as striae, feebly convex, the surface smooth but irregular, the punctures moderately coarse, close, confused, their anterior margins usually elevated, some rather coarsely crenulate at base. Declivity convex, rather steep; striae less strongly impressed; interstriae 1 and 3 moderately, 5, 7, 8 less strongly elevated, these and 6 armed by rather coarse teeth, those on 3 and particularly on 1 larger. 2 bearing two teeth near apex, 2 and 4 flat, finely punctured; interstria 1 bearing eight teeth, each only slightly compressed and usually with anterior profile evenly arcuate. 3 bearing 13 teeth with none of them compressed. Vestiture scanty, but stout, some setae almost scalelike.

Female.—Similar to male except from more strongly convex and more extensively granulate; pronotal lines and points much more abundant; a few elytral crenulations extend almost to declivity; declival teeth smaller with interstriae 2 and 4 armed by at least a few small teeth; declival vestiture largely of scales each only slightly longer than wide.

Type Locality.—Sixteen km. east Chiapa de Corzo, Chiapas, Mexico.

Host.—Juniperus sp.

Type Material.—The male holotype, female allotype, and 13 paratypes were collected at the type locality on June 17, 1961, at an elevation of about 2,300 m., No. 710, from a small _Juniperus_ branch.

The holotype, allotype and paratypes are in my collection.

_Chromesus gracilis_, n. sp.

This species is in the subgenus _Procramesus_ and is allied to _annectans_ Wood, but may be distinguished by the larger size, by the much more finely, shallowly punctured pronotum, by the smaller, shallow striae punctures, and by other characters.

Male.—Length 2.5 mm. (paratypes 2.2–2.7 mm.), 2.25 times as long as wide; color dark brown to black, with white vestiture.

Elytra rather deeply, concavely impressed from upper level of eyes to epistoma, the lateral margins rounded, bearing meshes of margin just above antennal bases, a pair of large squared prothoraces as in _annectans_; surface coarsely reticulate with a few fine, obscure punctures; vestiture fine, long, rather sparse. Antennal club acutely pointed.

Pronotum 0.9 times as long as wide; widest at base, sides weakly arcuate and converging slightly on basal two-thirds then rather strongly constricted before the broadly rounded anterior margin; surface reticulate, with fine, rather widely separated punctures, the punctures distinctly sulcate or subulate in lateral areas; vestiture consisting of stout semicircular bristles.

Elytra 1.5 times as long as wide, 1.9 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind, striae not im-
New Neotropical Scoyldidae

pressed, the punctures small, round, shallow, distinct; interstriae about three times as wide as striae, almost flat, smooth and shining with rather abundant, minute, setiferous, confused punctures and median rows of fine setiferous granules. Declivity steep, convex; striae weakly impressed; the interspaces feebly convex. Vestiture consisting of rather abundant, short, subplanose scales and interstitial rows of somewhat longer erect bristles, each bristle about two-thirds as long as distance between rows.

**Female.**—Similar to male except froms very shallowly impressed, the tubercles somewhat smaller; pronotal tubercles distinctly larger.

**Type Locality.**—University of Costa Rica Campus, San José, Costa Rica.

**Host.**—Bambusa vulgaris.

**Type Material.**—The male holotype, female allotype, and 83 paratypes were collected at the type locality on September 12, 1963, at an elevation of about 1,300 m., by S. L. Wood, from dead and dying stumps of Japanese bamboo which were 10 cm. or more in diameter. The diagonal, biramous, egg galleries were just under the surface of the wood. Larval mines were parallel to the grain of the wood.

The holotype, allotype, and paratypes are in my collection.

Chramesus ingens, n. sp.

Among the species known to me this one is unique in having the antennal bases comparably close together and higher than usual; in having the elytral vestiture fine and of uniform length; and in having the male frons not excavated, but the lateral margins elevated with the raised tubercle at a point well above the antennal insertion.

**Male.**—Length 2.7 mm. (paratypes 2.4-2.8 mm.). 1.6 times as long as wide; color dark brown or black. Frons impressed from upper level of eyes to epistoma with a low elevation between antennal bases, lateral margins elevated on middle third with a rounded tubercle just above antennal base; surface reticulate, with very fine punctures at sides and above; antennal bases closer together than eyes, distance from epistomal margin (omitting lobe) to antennal bases 1.6 times greatest width of eye; frons subglabrous. Antennal scape with small tuft of hair.

Pronotum 0.8 times as long as wide; base strongly bisinuate, basal angles broadly rounded, sides strongly arcuate, widest just behind middle, moderately constricted just behind the broadly rounded anterior margin; entire surface reticulate and with small, sparse, finely subanterior punctures, finer in postmedian area; glabrous.

Elytra 1.03 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal half, broadly rounded behind; striae narrowly impressed, the punctures small, distinctly impressed; interstriae about three times as wide as striae, slightly convex almost smooth with numerous, confused, small rounded setiferous granules. Declivity convex, moderately steep; about as on disc. Vestiture consisting of fine, erect, confused, hairlike setae, all of equal length, each shorter than a distance equal to width of an interspace (about two-thirds as long).

**Female.**—Similar to male except frontal margin feebly elevated and not armed; pronotal punctures almost entirely devoid of small asperities.

**Type Locality.**—Tapanti, Cartago Prov., Costa Rica.

**Host.**—Serjania mexicana? (probable error in identification).

**Type Material.**—The male holotype, female allotype, and 270 paratypes were collected at the type locality on October 24, 1963, at an elevation of about 1,300 m., by S. L. Wood, from a vine having three leaflets per leaf. The host was identified as Serjania mexicana, however, the tissues were very moist, soft and non-woody and turned black with age, suggesting an error in identification. This species was also collected at Puerto Viejo, Heredia Prov., and at Guapiles, Limon Prov., in humid lowland areas, but these specimens were not included in the type series.

The holotype, allotype, and paratypes are in my collection.

Chramesus acacicolens, n. sp.

Similar to crenatus Wood, but distinguished by the deeper, wider strial punctures, by the much shorter, wider, erect interstrial scales, by the small tubercles of elytral interspaces, and by other characters.

**Male.**—Length 1.8 mm. (paratypes 1.5-1.8 mm.). 1.65 times as long as wide; color light brown.

Frons broadly, concavely excavated from upper level of eyes to epistoma, deepest point near middle, subovate; lateral margins acute behind, armed by a pair of tubercles just below level of antennal insertion; surface coarsely reticulate, a few minute punctures scarcely visible; vestiture short, inconspicuous.

Pronotum 0.73 times as long as wide; median basal area produced slightly into scutellum notch, sides widest near base, rather strongly arcuate, constricted just behind the broadly rounded anterior margin; surface minutely rugulose, dull, rather finely, shallowly punctured, the punctures becoming finely asperate toward anterior and lateral areas; vestiture consisting of short, stout bristles.

Elytra 1.07 times as long as wide, 1.6 times as long as pronotum; sides straight and parallel on basal half, broadly rounded behind; striae impressed, the punctures rather large and deep; interstriae about twice as wide as striae, convex, with small, abundant, squamiferous punctures and median rows of tubercles that decrease in size posteriorly. Declivity convex, moderately steep; as on disc except punctures not evident. Vestiture consisting of abundant short scales and interstitial rows of erect scales slightly more than twice as long as ground vestiture, each large scale about three times as long as wide.

**Female.**—Similar to male except frons weakly convex, transversely impressed just above epistoma, minute punctures more evident; pronotal asperities evident only at anterolateral angles.

**Type Locality.**—Finca La Pacifica, 4 km.
northwest of Cañas, Guanacaste Prov., Costa Rica.

Host.—Acacia sp.

Type Material.—The male holotype, female allotype, and 80 paratypes were collected at the type locality on July 13, 1966, at an elevation of 50 m., by S. L. Wood, from the cambium region of branches and twigs of the host tree less than 2 cm. in diameter.

The holotype, allotype, and paratypes are in my collection.

Chlames varius, n. sp.

This is the only species of Chlames known to me in which the frons is concave in both sexes and the epistoma is armed in both sexes by a large median tubercle; the variegated color pattern of the scales is also unique in the genus.

Male.—Length 1.5 mm. (paratypes 1.4-1.7 mm.), 1.7 times as long as wide; color brown with light colored scales on basal fourth and lateral margins of pronotum and on interstriae 1 and lateral areas of elytral disc, dark scales predominate elsewhere.

Frons deeply, broadly, concave from eye to eye from well above eyes to epistoma; excavated area reticulate-granulate; lateral margin acute only at level of antennal bases, unarmed; epistomal margin bearing a large, pointed, median tubercle; vestiture consisting of moderately abundant, stout setae. Scape bearing a conspicuous tuft of long, yellow, subpubescent setae; club rather small for this genus, its apex not pointed.

Pronotum 0.92 times as long as wide; widest on basal third, the sides strongly, convergently arcuate toward the broadly rounded anterior margin; anterolateral areas with a few fine asperities; surface coarsely reticulate, the punctures rather fine, shallow, moderately close, many of them subulcinate on posterior area; basal margin biserulate; vestiture stout, short, essentially scale-like.

Elytra 1.14 times as long as wide, 1.6 times as long as pronotum; basae armed by 11 marginal crenulations on interstriae 2-9; scutellum not visible in usual sense; striae weakly impressed, stronger toward declivity, the punctures small, impressed; interstriae twice as wide as striae, convex, the surface evidently superficially reticulate, the punctures very fine, usually obscured by setae. Declivity convex steep; striae slightly deeper, interstriae slightly narrower than on disc. Vestiture consisting of moderately abundant, stout, almost scalelike, erect setae, and rows of erect scales each about twice as long as ground vestiture and about four or five times as long as wide.

Female.—Similar to male except frons more narrowly, shallowly concave with median tubercle a little smaller; pronotal crenulations larger and more numerous.

Type Locality.—Twenty-seven km. north of Ixmiquilpan, Hidalgo, Mexico.

Host.—Acacia sp.

Type Material.—The male holotype, female allotype, and 12 paratypes were collected at the type locality on July 10, 1967, elevation 1,900 m., No. 188, in an Acacia branch about 4 cm. in diameter, by S. L. Wood.

The holotype, allotype, and paratypes are in my collection.

Chlames semic, n. sp.

This species is exceedingly similar to varius Wood, described above, but differs by the larger size, by the uniformly light color of the vestiture, by the more finely sculptured pronotum, and by the shorter, more scalelike vestiture. This possibly could be a subspecies of varius.

Male.—Length 1.7 mm., 1.7 times as long as wide; color brown with white vestiture on pronotum and interstriae 1, tan elsewhere.

Exactly as in varius except as noted above and also setae on all margins of pronotum shorter and stouter; median extension of basal margin of pronotum less pronounced; elytral vestiture appearing more abundant and each seta conspicuously wider.

Type Locality.—Laguna Santa Maria, Nayarit, Mexico.

Type Material.—The unique male holotype was taken with a series of the following species on July 6, 1965, near 1,000 m. elevation. No. 201, by S. L. Wood. The host was a large woody vine (liana) having the larger stems square in cross section.

The holotype is in my collection.

Chlames unicornis, n. sp.

This species is rather closely allied to varius Wood, described above, but it is easily distinguished by the less extensive male frontal impression, by the smaller tuft of setae on the scape, by the subquadrate pronotum, by the more strongly impressed striae and strial punctures, and by the uniformly light colored vestiture.

Male.—Length 1.4 mm. (paratypes 1.3-1.6 mm.), 2.0 times as long as wide, color medium to light brown.

Frons deeply excavated from eye to eye from upper level of eyes to epistoma; lateral margin acute from just above level of antennal insertion to epistomal margin; surface rather coarsely reticulate above, becoming obscurely reticulate and shining below, armed by a large, pointed, median tubercle immediately above epistomal margin; vestiture sparse, inconspicuous. Antennal scape bearing a small tuft of fewer than a dozen long, yellow setae; club small for this genus.

Pronotum 0.83 times as long as wide; widest at base, the sides feebly arcuate and converging slightly on more than basal two-thirds, then rather abruptly constricted just before the broadly rounded anterior margin; surface rather coarsely reticulate, the punctures very close, rather shallow, irregular in outline, anterolateral asperities obscure. Vestiture consisting of short, rather abundant, stout, almost scalelike setae.

Elytra 1.2 times as long as wide, 1.5 times as long as pronotum; sides straight and subparallel on basal two-thirds to declivital base, then rather broadly rounded behind; basal margins armed by 11 crenulations; striae slightly impressed, the large punctures deeply impressed; interstriae as wide as striae, convex, each bearing a
row of fine, pointed tubercles. Declivity moderately steep, convex, essentially as on disc except area at junction of interstriae 3 and 9 slightly elevated. Vestiture consisting of moderately abundant, small, broad scales, and rows of erect interstitial scales about three times as long as ground cover, each half as long as distance between rows and almost equal in length to distance between erect scales within a row, about four times as long as wide; not longer on declivity.

**Female.**—Similar to male except from convex, coarsely reticulate to epistoma, the median tubercle absent and pronotal asperities slightly larger.

**Type Locality.**—Laguna Santa María, Nayarit, Mexico.

**Type Material.**—The male holotype, female allotype, and 76 paratypes were collected at the type locality on July 6, 1965, about 1,000 m. elevation, No. 201, from the phloem tissues of the host, by S. L. Wood. The host was a large woody vine (llana) about 7 cm. in diameter, having the cross-section of the larger stems square. Four paratypes were taken 25 km. west of Armaria, Colima, Mexico, on June 30, 1965, No. 143, from the same host, by S. L. Wood.

The holotype, allotype, and paratypes are in my collection.

**Chramesus cecropiae**, n. sp.

In this unique species the male frons is not excavated, but more nearly protubruntat at a level just above the antennal bases; in addition, the elytral ground vestiture is totally absent, a row of stout bristles marks each interstriae.

**Male.**—Length 1.25 mm. (paratypes 1.3 mm.), 1.7 times as long as wide; color rather dark brown, the elytra somewhat lighter.

Frons longitudinally flattened, transversely, weakly convex on upper third, then ascending rather abruptly above to an indefinite, strongly arcuate line between antennal bases, its median point well above (dorsad) its lateral extremities; lower two-thirds almost flat, the lateral margins below very slightly elevated; surface above coarsely reticulate, lower area transversely striate; vestiture consisting of a few hairlike setae on lateral areas on lower half. Antennal club moderately large for the genus.

Pronotum 0.82 times as long as wide; widest on basal third, sides arcuately converging to a slight constriction just before the rather broadly rounded anterior margin; surface shining, subbricate, with scattered, rather abundant tubercules of variable size on anterior three-fourths, some of those on anterolateral area finely asperate; a few large, obscure punctures evident toward base. Vestiture rather sparse, consisting of a few stout setae over entire surface.

Elytra 1.1 times as long as wide, 1.4 times as long as pronotum; elytral bases armed by about 12 crenulations; striae feebly if at all impressed, the punctures large, moderately deep, distinct; interstriae very slightly wider than striae, very slightly irregular, brightly shining, each bearing a row of small, pointed, seriferous tubercles. Declivity rather steep, convex, sculptured essentially as on disc. Vestiture consisting of rows of interstitial bristles, each bristle somewhat flattened toward its apex and equal in length to distances between bristles within and between rows; very minute strial hairs also evident.

**Female.**—Similar to male except frons more evenly convex, coarsely reticulate throughout, with a median low, on upper half, pronotal asperities larger, the tubercles largely absent but replaced by shallow, rather obscure punctures.

**Type Locality.**—Four km. southwest of Rincon, Osa Peninsula, Puntarenas Prov., Costa Rica.

**Host.**—*Cecropia* sp.

**Type Material.**—The male holotype, female allotype, and two paratypes were collected at the type locality between February 21 and 28, 1967, by D. D. Sliwa, from the fallen leaf petiole of a *Cecropia* tree.

The holotype, allotype, and paratypes are in my collection.

**Chramesus periusus**, n. sp.

Superficially this species resembles *vastus* Wood more closely than other species known to me, although its true affinities may lie nearer to *crenatus* Wood which shared the same host material. From *vastus* it differs by the more closely, deeply punctured pronotum, by the less strongly impressed striae, by the scalelike erect interstitial bristles, and in the male by the frontal impression extending above the eyes.

**Male.**—Length 2.2 mm. (paratypes 2.0-2.5 mm.), 1.4 times as long as wide, color brown.

Frons broadly concave from epistomial margin to just above upper level of eyes; lateral margins acutely elevated from just below upper level of eyes to epistomial margin, bearing a pointed tubercle at level of antennal insertion; surface reticulate except on smooth epistomial margin, the punctures small, shallow, obscure; vestiture fine, inconspicuous. Antennae as in related species.

Pronotum 0.73 times as long as wide; postero-lateral angles one-third pronotum length from base, median area produced posteriorly; sides wider at postero-lateral angles, strongly, arcuately convergent to moderate constriction just before the rather broadly rounded anterior margin; surgae finely reticulate, with fine, moderately deep, rather close punctures, about half of those in central area finely asperate, the asperities larger toward anterolateral angles; vestiture consisting of stout, rather short, recumbent bristles and similar, very fine hair.

Elytra 0.90 times as long as wide, 1.4 times as long as pronotum; anterior margins armed by low basally fused crenulations that merge lateral to striae 4 into a continuous costa; striae moderately impressed, the punctures small, moderately deep, rather widely spaced; interstriae about twice as wide as striae, weakly convex, a median row of fine, nongranulate punctures and confused minute punctures on each interstriae. Declivity rather steep, convex, sculpture essentially as on disc. Vestiture consisting of ground covering of small, non-overlapping, interstitial scales each longer than wide, and median rows of erect interstitial bristles, each twice as long as ground vestiture and four to five times as long as wide and spaced within a row by slightly more than length of a bristle.

**Female.**—Similar to male except frons not impressed, almost flat; lateral asperities on pronotum coarsely de-
veloped; each interstriae bearing a uniseriate row of coarse, narrow tubercles, each almost as high as wide.

**Type Locality.**—Five km, west of Jalitun, Vera Cruz, Mexico.

**Type Material.**—The male holotype, female allotype, and 56 paratypes were collected at the type locality on June 25, 1967, 50 m., No. 99, by S. L. Wood, from tunnels in the wood of branches 3-8 cm. in diameter. The host tree, awaiting identification, was also infested by *Chrysenus crenatus* and *Scolytus propinquus* Blandford.

The holotype, allotype, and paratypes are in my collection.

**Phloeotribus maurus**, n. sp.

This species resembles *sulcifrons* Chapuis and may be rather closely related; it is easily distinguished, however, by the large tuft of hair on the male scape, by the much coarser asperities on the anterolateral angles of the pronotum, by the coarser sculpture of pronotum and elytra, with some interstriae bearing only one row of interstitial crenulations, and by the median row of coarse setae on each of the interstriae.

**Male.**—Length 3.0 mm. (paratypes 2.3-3.1 mm.), 1.7 times as long as wide, color very dark brown to black.

Frons similar to but much narrower than in *sulcifrons*; sculpture similar; vestiture above antennal bases much coarser than in *sulcifrons*. Scape bearing a rather large, dense tuft of dark hair.

Pronotum outline as in *sulcifrons*; surface less uniformly, more deeply punctured, some punctures toward base much larger than in *sulcifrons*; anterolateral asperities about twice as large as in *sulcifrons*, the vestiture at lateral margins coarser and longer.

Elytra 1.05 times as long as wide; striae strongly impressed, the punctures clearly indicated; interstriae distinctly less than twice as wide as striae, the punctures subcuneulate on 2 and 3 to declivity, less distinctly so on 4 to 6, the crenulations uniseriate except somewhat biseriate at base of 2; interstriae narrower and more convex toward declivity. Declivity convex, moderately steep; interstriae narrower than on disc, each with a median, subcuneate row of low tubercles. Vestiture consisting of a row of short, subrect bristles on each interstriae; each bristle not longer than a third the distance between rows; largely abraded on basal half; some fine hair also on sutural interstriae.

**Female.**—Similar to male except frons convex, tovate just above level of antennal insertion; tuft of hair on scape absent.

**Type Locality.**—Near Rincon, Osa Peninsula, Puntarenas Prov., Costa Rica.

**Host.**—Ficus sp.

**Type Material.**—The male holotype, female allotype, and 30 paratypes were collected at the type locality on August 11, 1966, near 30 m., elevation. No. 63, from a *Ficus* limb 15 cm. in diameter, by S. L. Wood.

The holotype, allotype, and paratypes are in my collection.

**Phloeotribus atavus**, n. sp.

The large size, sculpture of the pronotum, and vestiture of pronotum and elytra serve to distinguish this species from all other representatives of the genus.

**Female.**—Length 3.6 mm. (paratypes 3.3-4.0 mm.), 2.9 times as long as wide; color very dark brown.

Frons shallowly, concavely impressed on lower two-thirds, the impression ending above in a small deep median fovea; lateral margins below antennal bases acute; surface rather coarsely reticulate above fovea, subreticulate to smooth below, the punctures small, deep, close; vestiture inconspicuous. Antennal club with segment 1 three times as wide as long, about as long as scape.

Pronotum 0.96 times as long as wide; widest at or just behind middle, sides rather strongly arcuate, converging very slightly anteriorly, rather strongly constricted just behind the rather broadly rounded anterior margin; surface completely devoid of asperities, reticulate, the punctures rather small, very close, deep; a faint median line weakly elevated; vestiture consisting of inconspicuous, very fine, short hair.

Elytra 1.4 times as long as wide, 1.8 times as long as pronotum; sides straight and parallel on basal two-thirds, broadly rounded and with apex rather narrowly extended on median third behind; striae narrowly impressed, the punctures rather obscure; interstriae twice as wide as striae, crenulate on basal half, some crenulations as wide as interspace, the elevations becoming narrower and uniseriate behind, some fine punctures also present; shining. Declivity rather steep, convex; striae impressed; interstriae convex. 1 slightly elevated on lower half, apical costal margin and posterior part of 9 also slightly elevated, each interspace with a row of small tubercles. Vestiture consisting of moderately sparse, small scales on posterior half of disc and on declivity, and sparser median interstrial rows of fine long hair, longest hairs equal in length to distance between rows and between adjacent hairs within a row.

**Male.**—Similar to female except frontal impression very slightly deeper and extending to upper level of eyes, the punctures larger, shallower; interspaces 1 and 2 on elytral declivity finely punctured and almost devoid of tubercles.

**Type Locality.**—Laguna Volcan Poas, Heredia Prov., Costa Rica.

**Hosts.**—Clusia sp. (type), and *Podocarpus oleifolius* (paratype).

**Type Material.**—The female holotype, male allotype, and 31 paratypes were collected at the type locality on October 6, 1963, at an elevation of about 2,700 m., by S. L. Wood, from a limb of *Clusia* about 25 cm in diameter. Three paratypes bear the same data but were taken July 14, 1963, from a *Podocarpus* root buttress. The egg tunnels were biramous, transverse, and almost entirely in the phloem. The species is aggressive; some specimens were attacking healthy living tissue, and it appeared to have killed several *Clusia* trees in the area.

The holotype, allotype, and paratypes are in my collection.
Phloeotribus hystrix, n. sp.

This species evidently is allied to discreps Blandford, although not closely related. It is distinguished by the more deeply striate elytra, by the more nearly scalelike vestiture, and by the declivital armature.

**Male.**—Length 1.7 mm. (paratypes 1.7-2.0 mm.), 2.1 times as long as wide; color brown.

Frons very shallowly concave below upper level of eyes, sides weakly elevated and armed at level of antennal insertion by a pair of small tubercles; surface coarsely reticulate, the punctures small, obscure; vestiture sparse, moderately long, coarse. Antennal club with segment 1 three times as wide as long.

Pronotum 0.9 times as long as wide; widest on basal half, the sides weakly arcuate, almost parallel on basal half, then converging to constriction just behind broadly rounded anterior margin; surface coarsely, deeply, closely, irregularly punctured, anterior and lateral areas subgranulate or even very finely asperate; vestiture short, stout, abundant, almost scalelike.

Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, obtusely angulate behind, with lateral declivital spines interrupting the profile; striae sharply impressed, the punctures large, deep, distinct; interstriae distinctly narrower than striae, irregular, each with a median row of fine setiferous granules and additional subgranulate setiferous punctures on each side. Declivity steep, convex; interspace 1 weakly elevated, 5 with two, 7 with three, 9 with five large pointed tubercles, the posterior most one on each interspace longer, 9 elevated slightly to final spine; costal margin near apex slightly elevated. Vestiture consisting of rather abundant interstrial subgranulate bristles, short except median row twice as long, erect; equally abundant on disc and declivity.

**Female.**—Similar to male except frons weakly convex, unarmed; pronotum more nearly asperate in lateral areas.

**Type Locality.**—Rio Damitas in the Dota Mountains, San José Prov., Costa Rica.

**Type Material.**—The male holotype, female allotype, and 20 paratypes were collected at the type locality on February 18, 1964, at an elevation of 700 m., by S. L. Wood, from the phloem tissues of twigs of Ficus glabrata; 35 paratypes bear identical data but were taken from Serjania triquetra; 1 bears the same data but is from Celtis iguanae; 16 paratypes were collected at the lower Rio Tempisque, Guanacaste Prov., Costa Rica, on March 25, 1964, at 15 m. elevation from Ficus twigs; 1 paratype is from Rio Damitas in the Dota Mountains, San José Prov., Costa Rica, taken on February 18, 1964, 200 m. elevation, from an unknown branch; and 1 paratype is from Palin, Esquinita Prov., Guatemala, taken on May 19, 1964, at 300 m. elevation, from a Ficus twig; all were collected by S. L. Wood.

The holotype, allotype, and paratypes are in my collection.

Phloeotribus oplusinus, n. sp.

As in demessus Blandford, except smaller, the basal margin of the pronotum straight, and the discal interstriae smooth and shining except for the uniseriate granules.

**Male.**—Length 1.4 mm. (paratypes 1.4-1.8 mm.), 1.8 times as long as wide; color dark brown, almost black, with light vestiture.

Frons deeply excavated from upper level of eyes to epistoma, deepest near center, the lateral margins acute from middle to antennal bases; surface rather coarsely reticulate; vestiture largely confined to marginal areas. Antennal scape long, ornamented by a tuft of long yellowish hair. Segment 1 of antennal club three times as wide as long.

Pronotum 0.8 times as long as wide; widest one-third length from base, sides rather strongly arcuate, anterior constriction weak, rather broadly rounded in front; surface coarsely, deeply punctured, spaces between punctures almost smooth, subshining, less than half the width of a puncture, with a small rounded, setiferous granule on anterior margin of each puncture; vestiture consisting of short, stout, whitish bristles.

Elytra 1.1 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, broadly rounded behind; single row of punctata on elytral base high, coarse; striae slightly impressed, the punctures coarse, deep; interstriae convex, narrower than striae, armed by a row of small setiferous tubercles. Declivity steep, convex; striae somewhat narrower and deeper, interspace 9 weakly elevated, more coarsely serrate. Vestiture consisting of uniseriate rows of subectret, flattened bristles, each bristle separated in its own row by distances equal to its own length, and from adjacent rows by distances about equal to one and one-half times its own length.

**Female.**—Similar to male except frons convex, the lateral margins rounded; and antennal scape without tufa of hair.

**Type Locality.**—Zamorano, Morazan, Honduras.

**Hosts.**—Ficus glabrata (type), Ficus spp. (paratypes), Celtis iguanae (paratype), and Ser- jania triquetra (paratype).

**Type Material.**—The male holotype, female allotype, and 39 paratypes were taken at the type locality on April 18, 1964, at an elevation of 700 m., by S. L. Wood, from the phloem tissues of twigs of Ficus glabrata; 35 paratypes bear identical data but were taken from Serjania triquetra; 1 bears the same data but is from Celtis iguanae; 16 paratypes were collected at the lower Rio Tempisque, Guanacaste Prov., Costa Rica, on March 25, 1964, at 15 m. elevation from Ficus twigs; 1 paratype is from Rio Damitas in the Dota Mountains, San José Prov., Costa Rica, taken on February 18, 1964, 200 m. elevation, from an unknown branch; and 1 paratype is from Palin, Esquinita Prov., Guatemala, taken on May 19, 1964, at 300 m. elevation, from a Ficus twig; all were collected by S. L. Wood.

The holotype, allotype, and paratypes are in my collection.

Phloeotribus squamatus, n. sp.

This unique species is distinguished from other species in the genus by the small size, by the unarmed pronotum, by the short, squamose vestiture, by the shallowly impressed male frons, and by other characters.

**Male.**—Length 1.25 mm. (allotype 1.3 mm.), 2.1 times as long as wide; color black, with white squamose vestiture.

Frons shallowly concave from upper level of eyes to epistoma, the lateral margins not acutely elevated...
or armed; epistomal margin weakly elevated, and with a median tubercle; surface coarsely reticulate; vestiture inconspicuous, mostly confined to marginal areas. Antennal club small, compact; segment 1 about 1.5 times as wide as long.

Pronotum 0.8 times as long as wide; widest just behind middle, sides moderately arcuate, moderately constricted just behind the rather narrowly rounded anterior margin; surface rather coarsely reticulate in cluding the punctures, with close, coarse, shallow punctures; vestiture consisting of suberect, short, stout, almost scalelike bristles, most of them about three times as long as wide.

Elytra 1.4 times as long as wide, 1.9 times as long as pronotum; crenulations of elytral base coarse, rather high, forming a single row; striae weakly impressed, the punctures large, rather deep; interstriae about half as wide as striae, almost restricted to a narrow row of closely set, subtruncate, squamiferous punctures. Dehiscency rather steep, convex; striae somewhat narrower and deeper than on disc. Vestiture consisting of imiseriate rows of almost parallel interstrial scales, each scale less than twice as long as wide; separated from adjacent scales in the same row by distances equal to less than the width of a scale, and between rows by distances equal to almost twice the length of a scale.

Female.—Similar to male except from convex, the median epistomal tubercle absent; vestiture of pronotum and elytra very slightly more slender.

Type Locality.—Tapanti, Cartago Prov., Costa Rica.

Type Material.—The male holotype and female allotype were collected at the type locality on July 8, 1963, at an elevation of 1,300 m., by S. L. Wood, from a dying tree that bore fruiting pods.

The holotype and allotype are in my collection.

Chaetophlebus phorodenri, n. sp.

This species has the same arrangement of crenulations at the base of the elytra as braziliensis (Blackman), but it differs by the much larger size, by the reduction of elytral striae, by the very different vestiture and by other characters.

Male.—Length 1.8 mm. (paratypes 1.5-2.0 mm.), 1.4 times as long as wide; color black, vestiture cinereus.

Froms broadly, deeply concave from vertex to the broad emarginate epistomal margin, and from eye to eye; surface granulose-retticulate; vestiture sparse in concavity, a few erect gray setae along sides below eye, margin above eyes ornamented by a row of long reddish hair many of which reach mandibles; mandibles each with an anterior extension half as large as mandible. Antennal club about as in braziliensis.

Pronotum 0.53 times as long as wide; widest at base, strongly arcuately converging to the broadly rounded anterior margin; surface reticulate, with small, rather close setiferous punctures; lateral areas armed by two groups of asperities; vestiture consisting of mixed slender and stout, short bristles and a few bidental hairs in lateral areas.

Elytra 1.1 times as long as wide, 2.1 times as long as pronotum; anterior margins armed by six pairs of crenulations, the median pair twice as wide as others, an additional submarginal pair at base of interspace 1; striae reduced, obscure, the punctures only slightly larger than those of interspaces; interspaces wide, flattened, with numerous punctures variable in size. Dehiscency steep, convex. Vestiture consisting of short, rather abundant, slender scales, and median rows of erect interstrial scales, each scale about three times as long as wide, separated from other scales in same row by distances equal to length of scale and between rows by one and one-half times length of a scale.

Female.—Similar to male except froms flattened, with a small median impression, frontal vestiture short, not specialized; pronotum armed by three paired groups of asperities.

Type Locality.—Zamorano, Morazan, Honduras.

Host.—Phoradendron robustissimum (type), and Phoradendron sp. (paratypes).

Type Material.—The male holotype, female allotype, and 40 paratypes were collected at the type locality on April 18, 1961, at an elevation of 700 m., by S. L. Wood, from twigs of the above mistletoe; 4 paratypes were taken at Cañas, Guanacaste Prov., Costa Rica, on April 10, 1966, from Phoradendron twigs; one paratype was taken 20 km. southeast of Liberia, Guanacaste Prov., Costa Rica, on July 10, 1966, from Phoradendron twigs; all were collected by S. L. Wood.

The holotype, allotype, and paratypes are in my collection.

Liparthrum americanum, n. sp.

This species is allied to squamosum (Blackman), but is readily distinguished by the much smaller, more strongly impressed elytral striae, and by the broadly concave male froms.

Male.—Length 0.8 mm., about 2.1 times as long as wide; color rather light brown.

Froms shallowly concave almost from eye to eye and from vertex to epistoma; surface reticulate; vestiture largely confined to impressed area, consisting of very fine, minute, abundant, pilose hair of uniform length.

Pronotum 0.8 times as long as wide; widest one-third from base, sides moderately arcuate, rather narrowly rounded in front; surface obscured by vestiture, evidently minutely subgranulate and with small setiferous granules uniformly distributed; vestiture consisting of stout, recurved bristles and erect broad scales in about equal numbers.

Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; bases armed by six pairs of crenulations between striae 4; striae not impressed, the punctures rather large, deep; interstriae almost as wide as striae, weakly convex, the moderately large, setiferous punctures imiserate, lecith granulate on anterior side. Dehiscency steep convex; striae and interstriae somewhat narrower than on disc. Vestiture consisting of strial rows of short recurved, stout hair, and interstrial rows of erect, broad scales, each scale almost as wide as long.

Type Locality.—The lower Rio Temques, Guanacaste Prov., Costa Rica.

Host.—Ficus sp.
Type Material.—The unique male holotype was collected at the type locality on March 25, 1964, at an elevation of about 20 m., by S. L. Wood, from small branches of the common narrow leafed fig that grew near the river.

The holotype is in my collection.

A second specimen, tentatively assigned to this species, possible the female, is identical to the type except the frons is less deeply, less extensively impressed and the pilose vestiture is not evident. It was taken at Dominical, Puntarenas Prov., Costa Rica, on December 9, 1963, from an unidentified branch.

Liparthrum cracentis, n. sp.

This species is allied to the four previously described American species but it may be distinguished by the small size, by the more slender body form, by the poorly developed female frontal vestiture, and by the narrower elytral scales.

Female.—Length 0.8 mm. (paratypes 0.75-0.85 mm.), 2.2 times as long as wide; color brown.

Frons moderately convex, slightly impressed just above epistomal margin; surface rather coarsely reticulate; vestiture sparse, more conspicuous toward epistoma, consisting of stout, subshining setae. Eye and antenna as in allied species.

Pronotum 0.81 times as long as wide; widest on basal third, sides weakly arcuate from base, converging on anterior half to the broadly rounded anterior margin; surface shining, feebly subreticulate, the obscure, setiferous punctures rather close, their anterior margins very finely asperate. Vestiture consisting of truncate, subangular scales, each about one and one-half times as long as wide, and equally abundant stout hairlike setae, each about one and one-half times as long as scales.

Elytra 1.6 times as long as wide, 1.96 times as long as pronotum; basal margins armed by five pairs of crenulations between interstriae; striae not impressed, the punctures coarse, rather deep; interstriae about half as wide as striae, the punctures fine, uniseriate, evidently not granulate. Declivity rather steep, convex; sculpture about as on disc. Vestiture consisting of strial rows of bristles equal in length to scales in interstrial rows; each scale almost as wide as a strial puncture and slightly longer than wide.

Male.—Similar to female except frons more broadly round, surface less reticulate, the obscure, setiferous punctures somewhat closer, only one pair of median bristles present on frons.

Type Location.—Twenty-nine km. west Niltepec, Oaxaca, Mexico.

Type Material.—The female holotype, male allotype, and 29 paratypes were collected at the type locality on June 23, 1967, at about 30 m. elevation, by S. L. Wood, from the pholom of a small tree having narrow, thick, waxy, simple leaves. The identification of the host is not yet available.

The holotype, allotype, and paratypes are in my collection.

Cnemonyx nitens, n. sp.

Evidently allied to atratus (Blandford), but distinguished by the more extensive frontal impression of the male, by the elongate pronotal punctures and minutely, longitudinally striose pronotal surface, and by the coarser interstrial punctures of the elytra.

Male.—Length 2.5 mm. (paratypes 2.0-2.5 mm.), 2.1 times as long as wide; color almost black.

Frons shallowly concave on median half from upper level of eyes to epistoma; surface reticulate above, the punctures rather coarse, deep, close, becoming finer and closer below in concave area; vestiture short and rather abundant in concave area, longer at sides of this area, evidently glabrous elsewhere. Antennal club subtriangular, finely, closely covered by hairlike pubescence; sutures not evident.

Pronotum 1.9 times as long as wide; widest at base, sides weakly arcuate and converging slightly to the slight constriction just behind the broadly rounded anterior margin; surface shining, shallowly etched by minute, longitudinally striose lines, becoming reticulate anteriorly, the punctures fine and elongate posteriorly, almost round and larger anteriorly and laterally; glabrous.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; sides straight and parallel on basal half, then arcately converging to the rather narrowly rounded, sutorially submarginate, posterior margin; striae 1 deep; others feebly impressed, the punctures rather small, deep, closer, interstriae smooth, shining, about twice as wide as striae; the punctures about half as large as those of striae, uniseriate behind, moderately confused on anterior half of disc; elytral bases with fine raised line; base of interspace 1 not depressed; scutellum small, as wide as long, almost flush with elytral surface. Declivity moderately steep, convex; striae and interstriae narrower than on disc, the striae narrowly impressed; interstriae moderately, broadly convex, shining except sutural half of 1 dull, the punctures uniseriate. Vestiture confined to declivity, consisting of sparse minute, short, suberect scales arising from interstrial punctures.

Cnemonyx insignis, n. sp.

This species evidently allied to panamensis (Blandford), but is distinguished by the larger size, by the procured epistomial carina, and by other characters.

Male.—Length 3.5 mm. (paratypes 3.5-3.9 mm.), 2.0 times as long as wide; color dark brown.

Frons shallowly concave on median two-thirds from upper level of eyes to epistoma; surface reticulate-granul-
late, and closely, deeply, rather coarsely punctured in concave area, shallowly, less closely punctured above; slightly less than median half of epistoma armed by an elevated, procurred, transverse carina; vestiture confined to concavity, consisting of short, erect, rather abundant, dark hair.

Pronotum 0.9 times as long as wide; widest at base, the sides weakly arnate and converging toward the rather broadly rounded anterior margin; surface smooth and shining on posterior three-fourths, with minute points and fine punctures, anterior fourth rather coarsely subreticulate, dull, faintly, longitudinally etched in lateral areas, the punctures very slightly larger in anterior area, much larger laterally; glabrous.

Elytra 1.1 times as long as wide, 1.2 times as long as pronotum; scutellum as wide as long, not depressed; basal margins of elytra with an irregular raised line; outline as for nitens, above; striae rather strongly impressed, the punctures fine, shallow, distinct; interstriae smooth, shining, at least twice as wide as striae, moderately convex at base, becoming rather narrowly costiform by declivital base, the punctures fine and uniserrate behind, confused toward base. Declivity moderately steep, convex; striae broadly impressed, the fine shallow punctures evident; interstriae narrowly, acutely, subcuneately elevated; striae and interstriae minutely reticulate-granulate; costal margin rather coarsely serrate. Rows of very minute interstrial scales evident on declivity.

Female.—Presumed the female is represented by specimens having the frons less strongly impressed, but otherwise similar to the male.

Type Locality.—Moravia, Cartago Prov., Costa Rica.

Type Material.—The male holotype, female allotype, and 5 paratypes were taken at the type locality on March 11, 1964, at an elevation of about 500 m., by S. L. Wood, as dead specimens under loose bark of an unidentified log about 40 cm. in diameter.

The holotype, allotype and paratypes are in my collection.

Cnemonyx opacus, n. sp.

This species, at least superficially, resembles insignis Wood, above, but is easily distinguished by the smaller size, by the narrow frontal carina, by the much more extensively granulate elytra, and by characters mentioned in the key. However, the antennal club has an entirely different shape and has three strongly procurred sutures clearly marked by rows of setae suggesting that the relationship is superficial at best.

Male.—Length 2.2 mm. (paratypes 2.0-2.5 mm.), 2.2 times as long as wide; color dark brown.

Frons shallowly concave on median half from upper level of eyes almost to epistoma, the surface closely, deeply, rather coarsely punctured; median fourth of epistoma bearing a strongly elevated, procurred, transverse carina; vestiture consisting of short, erect, rather abundant, stout hair in concave area. Antennal funicle with inner angle of segments projecting and bearing tufts of long yellow hair; club obovate, longer than wide, with three strongly procurred sutures conspicuously marked by rows of closely set setae.

Pronotum about as wide as long; widest on basal third, the sides rather weakly arnate and converging to the weak, transverse constriction just behind the rather narrowly rounded anterior margin; surface smooth and shining behind, becoming reticulate anteriorly and toward lateral margins, the punctures rather coarse, deep, somewhat larger in lateral areas; glabrous.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; sides straight and parallel on more than basal half, rather narrowly rounded behind; scutellum very small, rounded, not depressed; basal margins of elytra marked by a fine, irregular, raised line; striae impressed, the punctures rather large, deep, clearly impressed in basal area, obscure behind; interstriae convex, finely, completely granulate (including striae) posteriorly, coarsely punctured on basal third of disc. Declivity moderately steep, convex, striae deeply impressed, the punctures obscure; interstriae narrow, strongly convex, minutely granulate, finely subcuneate; interspace 9 moderately elevated, continuing to apex, highest at junction with 3. Vestiture confined to declivity, consisting of uniserrate rows of minute interstrial scales.

Female.—Similar to male except frons less strongly impressed, almost flat.

Type Locality.—Playa del Coco, Guanacaste, Costa Rica.

Host.—Hippomane mairicella.

Type material.—The male holotype, female allotype, and 64 paratypes were collected at the type locality on October 18, 1963, at sea level, by S. L. Wood, from the bark of the above host tree. This aggressive species constructs biramous, transverse, egg tunnels in the bole and branches of the host tree. Adult and the irregular larval tunnels were almost entirely in the phloem tissues.

The holotype, allotype, and paratypes are in my collection.

Cnemonyx gracilens, n. sp.

This species is very closely related to exilis Wood, but it may be distinguished by the smaller size, by the more broadly impressed frons with the epistomial carina higher, by the less numerous, more nearly oval pronotal punctures, and by the shorter, finer, less strongly flattened elytral setae.

Male.—Length 1.3 mm. (paratypes 1.2-1.4 mm.), 2.6 times as long as wide; color dark brown.

Frons as in exilis but more broadly planoconcave, the transverse epistomial carina less procurred, slightly higher, occupying at least two-thirds width of epistomial margin. Acumen sometimes present, perhaps a little more abundant.

Pronotum 1.09 times as long as wide; punctures distinctly less numerous than in exilis, each about one and one-half times as long as wide. Glabrous.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; as in exilis interstrial bristles on declivity much shorter, very weakly or ot at all flattened, narrower, not increasing in width apically.

Female.—Similar to male except frons less strongly impressed.

Type Locality.—Fifty-seven km. southeast of
El Cameron, Oaxaca, Mexico.

**Type Material.**—The male holotype, female allotype, and 98 paratypes were collected at the type locality on June 22, 1967, No. 81, by S. L. Wood. Specimens were taken from phloem tissues of twigs of a small tree that had peeling bark, thin simple leaves, and abundant white latex; a sample awaits identification.

The holotype, allotype and paratypes are in my collection.

*Ctenomyx recusus*, n. sp.

This species is allied to *impressus* Wood, but it is readily distinguished by the larger size, by the much more strongly impressed frons and by the dull pronotal surface.

**Male.**—Length 1.7 mm. (paratypes 1.5-1.8 mm.). 2.1 times as long as wide; color dark reddish brown.

Frons broadly, rather deeply concave from just below upper level of eyes to epistomal margin; concavity densely pubescent, the setae moderately, uniformly long; surface of marginal areas and above coarsely reticulate, with fine, close punctures; surface in concavity obscured by pubescence. Scape short; funicle bearing a dense tuft of long hair; club obovate, with three strong procured sutures marked by setae, 1 extending almost two-thirds club length from base.

Pronotum 0.92 times as long as wide; basal margin bisinuate, marked by a fine, raised line; widest at base, arcately converging to a slight constriction just before the broadly rounded anterior margin; surface dull, minutely, longitudinally echid, the punctures fine, ovate, close, moderately deep. Glabrous.

Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather narrowly rounded behind; basal margins indistinctly raised along a fine line; striae impressed, the punctures fine, distinctly impressed; interstriae almost twice as wide as striae, convex, dull, each with a uniseriate (confused on 2) row of fine, short, transverse crenulations, the puncture posterior to each crenulation fine, obscure. Declivity convex, moderately steep; about as on declivity, with interstriae 9 weakly elevated and more coarsely tuberculate, 10 with a row of fine tubercles posteriorly. Vestiture confined to declivity, consisting of interstrial rows of very short, flattened bristles each about twice as long as wide.

**Female.**—Similar to male except frons very slightly less strongly impressed.

**Type Locality.**—Forty-eight km. east of Tehuantepec, Oaxaca, Mexico.

**Type Material.**—The male holotype, female allotype, and 87 paratypes were collected at the type locality on June 22, 1967, 120 m., No. 81, by S. L. Wood. The host was s small tree with simple leaves; a sample awaits identification.

The holotype, allotype, and paratypes are in my collection.

A series taken from “Leche Sillo,” 16 km. northwest of Acatlan, Puebla, Mexico, June 15, 1967, 1,700 m., No. 36, by S. L. Wood, not designated as paratypes, have the posterior half of the pronotum smooth and shining, and the punctures behind the interstrial crenulations are more conspicuous. The series overlap in these characters to such an extent that geographical races cannot be designated.

*Caenopleurus infidellis*, n. sp.

This species is allied to *auricomus* Blandford, but is not closely related. It differs in the female by the more strongly convex frons above, and narrower below, by the much less closely punctured pronotum, by the more sparsely punctured elytra, by the near absence of elytral scales, by the smaller size, and by other characters.

**Female.**—Length 2.7 mm. (paratypes 3.2 mm.). 20 times as long as wide; color black.

Frons rather strongly convex above, more nearly flattened below, with a distinct, transverse impression just above epistomal margin; surface rather coarsely reticulate and with rather abundant, shallow, indefinite punctures; vestiture sparse, inconspicuous. Antenna essentially as in *auricomus*.

Pronotum 0.98 times as long as wide; widest near base, sides rather weakly arcuate and converging slightly to the rather strongly rounded anterior angles, broadly rounded in front; surface minutely reticulate and dull on anterior half, almost smooth and subshining behind; the punctures minute, sharply impressed, separated by distances equal to two or more diameters of a puncture; glabrous.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; widest at base, the sides converging posteriorly to the narrow, submarginate posterior margin; striae not impressed, the punctures small, shallow, rather widely spaced; interstriae twice as wide as striae, shining, somewhat irregular, very sparsely punctured, the shallow punctures almost as large as those of striae. Declivity gradual, convex; striae weakly impressed. Vestiture consisting of very sparse interstrial scales on sides and declivity.

**Male.**—Not represented in the material at hand.

**Type Locality.**—Peralta, Cartago Prov., Costa Rica.

**Type Material.**—The female holotype and one female paratype were collected at the type locality on March 10, 1964, at an elevation of about 500 m., by S. L. Wood, from a dead tree seedling 1 cm. in diameter. The egg tunnel followed the central axis of the host for several centimeters, the larval cradles extended into the wood at an acute angle to the central axis. Two adult females and small larvae were in the only tunnel found.

Both specimens are in my collection.

*Scolytus nodatus*, n. sp.

Fig 1

In the American *Scolytus* fauna this species is unique. The female abdominal sternae are unarmed; in the male sternum 2 is armed by a large median tooth, 4 is armed by a large, median, rounded knob, and the lateral margins of 2 and 3 are each armed by a pair of small teeth; the frons is convergently aciculate and pubescent in
both sexes, it is devoid of tubercles in both sexes.

Male.—Length 3.8 mm. (paratypes 3.1–3.8 mm.), 2.0
times as long as wide; color dark brown, anterior margin
of thorax, bases and apices of elytra may be reddish.

Frons weakly convex; surface coarsely, somewhat con-
vergently striose toward the shallowly, broadly emar-
ginate epistomal margin; punctures not evident; vestiture
consisting of fine, rather long, moderately abundant hair.
Eye emarginate; very finely granulate. Antennal club
2.0 times as long as wide; sutures not evident, very finely,
closely pubescent.

Pronotum equal in length and width; widest at
base, the sides moderately arcuate and converging to dis-
tinct constriction just behind broadly rounded anterior
margin; surface smooth, brightly shining, the punctures
rather small, deep, oval, larger in lateral and anterior
areas; glabrous on disc, sparse hair at sides and in front.

Elytra 1.1 times as long as wide, 1.1 times as long as
pronotum; sides straight and parallel on basal half, con-
verging slightly behind to the broadly rounded postco-
lateral angles, almost straight on median half; posterior
margin smooth, striae and interstriae moderately im-
pressed, the punctures small, rather deep, those of striae
very slightly larger; elytra descending very slightly near
posterior margin; vestiture confined to scutellar impres-
sion. Sternum 2 ascending sharply, the margin not pro-
duced, armed by a laterally compressed, median spine,
its base extending from anterior margin to middle of
segment, longitudinal length of base and height of spine
about equal; sternum 4 armed by a large, rounded
-tubercle, 2 and 3 each armed at lateral margins by a
pair of small teeth; surface finely, obscurely punctured,
dull except anterior half of 2 shining; pubescence sparse,
hairlike.

Female.—Similar to male except frons more nearly
flat; all abdominal sternum unarmed.

Type Locality.—Santa Ana, San José Prov.,
Costa Rica.

Type Material.—The male holotype, female
allotype, and 4 paratypes were taken at the type
locality on November 8, 1963, at an elevation of
1,300 m., by S. L. Wood, from the limb of an
unidentified tree. Nineteen other paratypes
were collected at Fort Clayton, Panama Canal
Zone, on December 22, 1963, at an elevation of
30 m., by S. L. Wood, from a large, woody vine
(Iana) about 5 cm. in diameter.

The holotype, allotype, and paratypes are
in my collection.

Scolytus cristatus, n. sp.

Fig. 2

This species does not appear to be closely
related to any known Neoptopical representa-
tive of the genus. The frons of both sexes is con-
 vex, convergently striose, with a very fine, low,
long, median, subcarinate ridge, and in the male
moderately abundant, uniformly distributed,
long, frontal hair; the second abdominal sternum
ascends rather abruptly, not sharply, and is
armed by a high, narrow carina on anterior two-
thirds, its highest point near its posterior
extremity.
New Neotropical Scolytidae

Fig. 2.
Scolytus cristatus posterolateral aspect of male abdomen.

Male.—Length 2.4 mm. (paratypes 2.3-2.7 mm.). 2.0 times as long as wide; color reddish-brown (mature paratypes dark reddish-brown).

Frons convex, somewhat flattened below; surface convergently strigose, the grooves usually wider than the ridges, the median ridge higher, subcarinate, extending from epistomal margin almost to upper level of eyes; vestiture fine, long, rather abundant, uniformly distributed.

Pronotum very slightly wider than long; widest on basal third, sides moderately arcuate and converging slightly to constriction just behind the broadly rounded anterior margin; surface smooth, shining, with some very minute points and rather widely separated, moderately small, deep, oval punctures, the punctures larger in lateral areas and in front; glabrous.

Elytra 1.1 times as long as wide, 1.2 times as long as pronotum; striae and interstriae strongly, equally impressed, the punctures moderately large, shallow, the ridges between rows of punctures smooth, shining, convex, almost as wide as grooves; declivity descending slightly; a few scattered, slender scales on declivity. Venter with sternum 2 ascending abruptly, not sharply, armed by a median, laterally compressed, rather high elevation extending from near anterior margin of segment two-thirds of its length, highest point on elevation near its posterior limits; sternum 2 very coarsely, shallowly punctured, the surface within each puncture reticulate, the interspaces subreticulate; sternum 3 with one row of punctures, 4 and 5 not clearly punctured, dull.

Female.—Similar to male except frons subglabrous; carinate armature of sternum 2 not as high, occupying middle third of length of segment.

Type Locality.—Lower Rio Tempisque, Guanacaste Prov., Costa Rica.

Type Material.—The male holotype, female allotype, and 29 paratypes were collected at the type locality on March 25, 1964, at an elevation of about 20 m., by S. L. Wood, from the bark of an unidentified broken branch. The transverse, binamous egg tunnels engraved the wood rather deeply; larvae were not present.

A series of this species, not included in the type series, was collected 8 km. south of Atenguique, Jalisco, Mexico, on June 25, 1965, from an unidentified woody vine (liana).

The holotype, allotype, and paratypes are in my collection.

Microborus limatus, n. sp.

This species differs from all previously described representatives of this genus by the more narrowly rounded (subangulate) posterior margin of the elytra, by the more gradual elytral declivity, and, particularly, by the brightly shining subglabrous elytral surface with the sparse, declivital, hairlike setae that are separated from one another by one to two or more times the length of a seta.

Male.—Length 1.4 mm. (paratypes 1.3-1.5 mm.), 2.7 times as long as wide; body color dark brown, elytra medium brown.

Frons narrow and feebly convex between eyes, protruding very slightly just above antennal bases; surface smooth and polished, with a few scattered, minute punctures; almost glabrous. Eyes very large, almost touching below; anterior margin very broadly emarginate; very coarsely faceted. Antennal scape short, about twice as long as pedicel; funicle 6-segmented; club subglobular, sutures obscurely marked by rows of setae.

Pronotum 1.25 times as long as wide; sides almost straight and parallel on basal three-fourths, rather broadly rounded in front; anterior angles not narrowed; surface shining, weakly reticulate, the punctures rather small and shallow, separated from one another by one to two diameters; glabrous.

Elytra 1.9 times as long as wide; sides almost straight and parallel on basal three-fourths, narrowly (subangulately) rounded behind; striae 1 moderately, 2 weakly impressed, narrow, the punctures small, separated by distances equal to their own diameters; interstriae distinctly wider than striae, smooth, brightly shining, each with a sparse row of minute punctures. Declivity rather steep, not precipitous; striae and interstriae about as on disc, except interstrial punctures very finely granulate; interstriae 7 and 9 acutely elevated from declival base to point of fusion, the acute elevation continuing to apex. Vestiture short, sparse, almost entirely restricted to declivity; each hairlike seta about equal to half the width of an interspace, and separated from one another by about one and one-half to two times the length of a seta.

Female.—Similar to male except more finely sculptured; the declivital granules scarcely visible.

Type Locality.—Finca Gromaco on Rio Coto Brus (34 km. from mouth), Puntarenas Prov., Costa Rica.

Type Material.—The male holotype, female allotype, and 11 paratypes were taken at the type locality on July 14, 1963, at an elevation of about 500 m., by S. L. Wood, from the phloem tissues of a large limb of an unknown tree that had been cut at the margin of the jungle.

The holotype, allotype, and paratypes are in my collection.

Microborus ambiguus, n. sp.

This species is closely related to limatus Wood, described above, but it may be distingushed by the slightly deeper pronotal punctures, by the impressed, much more coarsely punctured declival striae, and by the fine interstrial granules on the declivity.

Female.—Length 1.3 mm. (paratypes 1.3-1.4 mm.), 2.9 times as long as wide; color of head and pronotum very dark brown, posterior areas and legs reddish brown.
Head, pronotum, and elytral disc as in *limatus* except, as noted above, the pronotal punctures slightly deeper. Elytral declivity convex, steep; striae slightly impressed, the punctures coarse, deep; interstriae slightly narrower than striae, very slightly convex, each bearing a uniseriate row of fine granules; interstriae 7 very acutely, strongly elevated, joining 9 and continuing but declining in height slightly along costal margin to sutural apex, 9 narrowly, not strongly elevated from level of hind coxae to junction with 7. Vestiture confined to declivity, consisting of interstitial rows of fine, short, almost hairlike bristles.

**Male.**—Although both sexes are probably represented in the series sexual differences are not apparent.

**Type Locality.**—Twenty-five km east of Coatzacoalcos, Veracruz, Mexico.

**Type Material.**—The female holotype and two paratypes were collected at the type locality on June 26, 1967, 30 m., No. 110, by S. L. Wood. Three paratypes were taken 22 km. west of Cardenas, Tabasco, Mexico on June 26, 1967, 30 m., No. 106, by S. L. Wood. Both series were taken from phloem tissues of limbs and bole 10-20 cm. in diameter of the same unidentified species of cut tree.

The holotype and paratypes are in my collection.

*Scolytodes (s. str.) clusiae*, n. sp.

Evidently not closely related to previously known species. It has interstriae 10 ending before level of metacoxae, the protibiae armed by a small tooth on posterior face just before tarsal insertion and between terminal macro and first or second marginal tooth; female frons broadly, shallowly concave.

**Female.**—Length 1.8 mm. (paratypes 1.7-1.9 mm.), 2.4 times as long as wide; color black.

Frons broadly, shallowly concave from upper level of eyes to level of antennal insertion; surface closely, deeply, somewhat coarsely punctured over entire frontal area in and out of concavity; median epistomal lobe conspicuous, broad, short, continuous with surface of frons; vestiture very fine, not abundant, longer above, not evident along epistoma.

Pronotum 1.0 times as long as wide; widest at base, very slightly constricted one-third from base, weakly arcuate on anterior half then broadly rounded in front; surface reticulate, with fine, obscure, rather widely spaced punctures on posterior half, equally fine sparse, minute granules on anterior third; almost glabrous.

Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; widest one-third from base, the sides feebly arcuate, abruptly rounded at declivital base, narrowly rounded behind; striae not impressed, the punctures very small, not deep; interstriae about twice as wide as striae, shining, irregular due to obscure surface lines, the punctures not evident. Declivity convex, rather steep; striae 1 weakly impressed above, the punctures on all striae obscurely indicated. Vestiture consisting of a few rather short hairs and, on lower half, more numerous, very short, semirecumbent hair.

**Male.**—Similar to female except frons rather strongly convex, finely, obscurely punctured, surface reticulate, vestiture sparse, short, inconspicuous; strial punctures rather obscure.

**Type Locality.**—Summit of Volcan Poas, Heredia Prov., Costa Rica.

**Host.**—*Clusia* sp.

**Type Material.**—The female holotype, male allotype, and 16 paratypes were collected at the type locality on August 19, 1966, by S. L. Wood, from green phloem of dying twigs of the common *Clusia* tree in the area.

The holotype, allotype, and paratypes are in my collection.

*Scolytodes (s. str.) volcanus*, n. sp.

Closely related to *clusiae* Wood, described above, but smaller, the small tooth on posterior face of protibiae absent, the strial punctures larger, and the female frons more narrowly impressed to vertex.

**Female.**—Length 1.3 mm. (paratypes 1.2-1.4 mm.), 2.3 times as long as wide; color very dark brown, almost black.

Frons narrowly, shallowly concave from epistomal margin to above upper level of eyes; surface finely, shallowly but distinctly, densely punctate, epistomal lobe mostly shining; vestiture largely confined to margin of impressed area, fine, short, somewhat longer, more abundant, minute in concavity.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on basal half, then somewhat arcuate and rather narrowly rounded in front; surface reticulate, the punctures fine, sparse, rather obscure, devoid of granules; glabrous.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, narrowly rounded behind; striae not impressed, the punctures moderately large, deep; interstriae slightly wider than striae, shining, with very few lines, the punctures obscure, mostly obliterated. Declivity rather steep, convex; an occasional deep, interstrial puncture present; shining Glabrous.

**Male.**—Similar to female except frons concave, reticulate, obscurely punctured, the vestiture greatly reduced, inconspicuous; a few interstrial punctures clearly impressed.

**Type Locality.**—Volcan Poas, Heredia Prov., Costa Rica.

**Type Material.**—The female holotype, male allotype, and 24 paratypes were collected at the type locality on July 14, 1963, 100 m. (elevation) below the summit, by S. L. Wood, from a small woody vine and cut tree seedlings.

The holotype, allotype, and paratypes are in my collection.

*Scolytodes (s. str.) parvulus*, n. sp.

Similar to *volcanus* Wood, described above, but smaller, the female frons armed by a pair of longitudinal carinate, the strial punctures reduced; the female frontal vestiture uniformly distributed.

**Female.**—Length 1.1 mm. (paratypes 0.9-1.1 mm.), 2.3 times as long as wide; color rather dark brown.
Frons flattened from upper level of eyes to epistoma, the median half of each side just inside of lateral margin armed by a shining longitudinal carina; the pair of carinæ beginning at level of antennal insertion and ending before upper level of eyes; surface finely, rather closely punctured in impressed and lateral areas, reticulate above eyes; vestiture fine, moderately long around margin, somewhat shorter in central area, moderately abundant.

Pronotum 1.0 times as long as wide; sides very weakly arcuate and feebly narrowed anteriorly on basal two-thirds, broadly rounded in front; surface reticulate, with sparse, minute punctures extending from base to anterior margin; glabrous.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal half, rather narrowly rounded behind; striae 1 weakly impressed, others not at all impressed, the punctures fine, shallow, rather obscure; interstriae wider than striae, not entirely smooth, the punctures sparse, fine, obscure. Declivity convex, steep; essentially as on disc but interspaces narrower and punctures smaller, the features not sharply defined. Vestiture consisting of less than a dozen moderately long, erect interstrial bristles.

Male.—Similar to female except frons convex, with a slight transverse impression just above epistoma, surface obscurely reticulate, shining, sparsely punctured, vestiture very sparse, mostly near epistoma; pronotum obscurely reticulate, subshining.

**Type Locality.**—Pandora, Limon Prov., Costa Rica.

Host.—*Cecropia* sp.

**Type Material.**—The female holotype, male allotype, and 14 paratypes were collected at the type locality on August 22, 1963, at an elevation of about 250 m., by S. L. Wood, from the petioles of fallen *Cecropia* leaves. Other paratypes were taken from the same host material, by S. L. Wood, as follows: 17 from Barro Colorado Island, Panama Canal Zone, December 27, 1963, elevation about 70 m.; 11 from Palín, Esquintla Prov., Guatemala, May 19, 1964, elevation 350 m.; 1 from Rincon de Osa, Puntarenas Prov., Costa Rica, August 11, 1966, elevation 30 m.

The holotype, allotype, and paratypes are in my collection.

**Scolytodes irazuensis**, n. sp.

Rather closely related to *parvulus* Wood, described above, but larger, the female frons only shallowly impressed with setae on vertex extending half the distance to the antennal insertion, and the general sculpture coarser.

Female.—Length 1.7 mm. (paratypes 1.5-1.9 mm.), 2.4 times as long as wide; color very dark brown. Frons rather broadly, longitudinally impressed from upper level of eyes to epistoma; the lateral margins above level of antennal insertion subaracnately elevated almost to upper level of eyes; surface finely, closely, deeply punctured; vestiture mostly confined to vertex, rather long, moderately abundant (largely abraded in type), none of setae long enough to reach half the distance to level of antennal insertion, only a few setae arise below upper level of eyes.

Pronotum 1.0 times as long as wide; sides weakly arcuate and converging slightly on basal two-thirds, rather broadly rounded in front; surface reticulate, rather coarsely, shallowly, not closely punctured, the punctures intermixed with very minute asperities on the rather strongly declivous anterior fourth; glabrous.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, the punctures small, not sharply defined; interstriae almost twice as wide as striae, the punctures small, deep, almost uniseriate. Declivity convex, steep; strial and interstitial punctures smaller than on disc, rather deep. Vestiture consisting of less than a dozen widely scattered, erect, hairlike bristles on disc and declivity, mostly on interspace 3.

Male.—Similar to female except frons convex with a slight impression above epistoma, obscurely reticulate, indistinctly punctured; strial and interstitial punctures much less clearly defined on disc and declivity.

**Type Locality.**—Volcan Irazu, Cartago Prov., Costa Rica.

Host.—*Oreopanax xalapense* (type), and at least two other tree species.

**Type Material.**—The female holotype, male allotype, and 29 paratypes were taken at the type
locality on June 28, 1963, at an elevation of 2,800 m., by S.L. Wood, from the phloem of *Oreopanax xalapense* branches. Other paratypes taken at the same locality by the same collector include: 32 taken July 13, 1963, from an unidentified branch; 38 taken October 26, 1963, from the boles of *Oreopanax nigigenus* and also from another tree, at an elevation of 2,500 m.

The holotype, allotype, and paratypes are in my collection.

*Scolytodes* (s. str.) *cecropicolens*, n. sp.

In size and proportions this species is more nearly similar to *maurus* (Blandford) than to other species known to me, but tibial and other characters are very different.

**Female.**—Length 2.0 mm. (paratypes 1.9-2.2 mm.), 1.9 times as long as wide; color medium brown, with marginal areas darker, paratypes range to dark brown.

Frons rather narrowly flattened below upper level of eyes, median third on lower two-thirds of flattened area rather abruptly impressed, the impression wider below and less definite; lateral margins indefinitely elevated below level of antennal insertion; surface reticulate above, subreticulate in impressed area, the punctures coarse, sparse, sharply defined but not very deep; vestiture minute, inconspicuous, a few longer hairlike setae on epistoma.

Pronotum 0.96 times as long as wide; widest at base, sides very slightly arcuate, converging slightly to the subapart anterolateral angles, rather narrowly rounded in front; anterior third feebly asperate; surface reticulate, the punctures rather coarse and separated by more than their own diameters, much finer anteriorly, continuing to anterior margin; vestiture minute, appearing glabrous.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae feebly, if at all impressed, the punctures rather coarse, moderately deep; interstriae slightly more than twice as wide as striae, weakly convex, the punctures almost as large as those of striae, those on 2 and 4 confused on basal half, almost uniseriate elsewhere. Declivity convex, rather steep; the punctures of striae and interstriae smaller, shallower, and less sharply defined than on disc. Vestiture consisting of rows of short interstrial hair; very minute strial setae visible toward base of elytra.

**Male.**—Similar to female except frons convex, with a slight transverse impression just above epistoma.

**Type Locality.**—Peralta, Cartago Prov., Costa Rica.

**Host.**—*Cecropia* sp.

**Type Material.**—The female holotype, male allotype, and 151 paratypes were collected at the type locality on October 24, 1963, at an elevation of 1,300 m., by S. L. Wood, from the bark and pith of a branch 5 cm. in diameter.

The holotype, allotype, and paratypes are in my collection.

**Habits.**—As in all other *Scolytodes* species known to me, this species is monogamous. The adult male constructs an entrance tunnel and begins a nuptial chamber. Both male and female enlarge the oval cavity to about 3.5 mm. wide and about 5.8 mm. or more long. It is entirely within the thin bark, not engraving the wood at all; only the paper-thin, smooth outermost layer of bark remains to conceal the tunnel. Eggs are scattered indiscriminately in the chamber; the young larvae feed along the margins of the chamber through the first and second instars, enlarging it somewhat. While the young larvae feed the parent beetles bore from the phloem through the woody tissues to the large pith area. In the pith they construct a new chamber that is usually slightly larger than the first. Third instar larvae (as judged by their size) migrate to the pith...
Scolytodes (s. str.) cecropiavorus, n. sp.

Closely related to cecropii Schell, but it is distinguished by the distinctly impressed strial and interstitial punctures, by the shining male frons with fine punctures, and by the more widely separated female frontal carinae.

**Female.**—Length 1.7 mm. (paratypes 1.4-1.8 mm). 2.2 times as long as wide; color very dark brown.

Frons flattened from vertex to epistoma, divided on lower half into almost equal thirds by a pair of prominent, subparallel, longitudinal carinae; surface finely, rather closely punctured, and punctures somewhat sparse between carinae; lateral and upper areas ornamented by a rather sparse tuft of fine, long, yellow hair.

Pronotum 1.0 times as long as wide; widest near base, the sides weakly arcuate, converging very slightly to anterior fourth, then rather narrowly rounded in front; surface reticulate, with fine, rather sparse punctures; glabrous.

Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae 1 feebly, others not at all impressed, the punctures small, shallow; interstriae almost three times as wide as striae, obscurely marked by minute points and lines, the punctures fine, obscure, uniseriate. Declivity moderately steep, convex; strial and interstitial punctures obscurely indi-

cated. Glabrous, except for a few small setae along costal margin.

**Male.**—Similar to female except frons even more convex, with a weak transverse impression just above epistomal process, the surface subreticulate above, subshining below, glabrous, except a few setae near epistoma.

**Type Locality.**—San Ignacio de Acosta, San José Prov., Costa Rica.

**Host.**—Cecropia peltata.

**Type Material.**—The female holotype, male allotype, and 12 paratypes were collected at the type locality on July 5, 1963, at an elevation of 1,500 m., by S. L. Wood, from leaf petioles of the above host. The tunnels were just below the epidermal layer along the main shaft of the petiole. Additional paratypes were taken in Costa Rica as follows: 17 at Rio Damitas in the Dota Mts., San José Prov., July 22, 1963, 250 m., and 4 at Rincon de Osa, Puntarenas Prov., August 11, 1966, 30 m.; all were taken from the same host by the same collector.

The holotype, allotype, and paratypes are in my collection.

**Scolytodes cecropiavorus acuminatus, n. subsp.**

This subspecies is identical to cecropiavorus Wood, described above, except that the elytral apex is strongly acuminate and the male frons is more strongly convex. The hosts and habits are the same. Intergradation between the two forms could not be demonstrated with the limited material at hand.

**Type Locality.**—Tapanti, Cartago Prov., Costa Rica.
Type Material.—The female holotype, male allotype, and 7 paratypes were collected at the type locality on October 24, 1963, at an elevation of 1,300 m., by S. L. Wood.

The holotype, allotype, and paratypes are in my collection.

Scolytodes cecropiavorus punctifer, n. subsp.

Male.—A series of males that must represent a geographic race of cecropiavorus was taken from a different, undetermined species of Cecropia. This subspecies is of the same size and proportions as cecropiavorus but the elytral apex is more broadly rounded, the declivital punctures are strongly impressed, and the male frons is sparsely, minutely punctured below and shining. The habits are the same. Intergradation between the two forms could not be demonstrated from the limited material at hand.

Type Locality.—Gatun Dam, Canal Zone, Panama.

Type Material.—The male holotype and 29 paratypes were collected at the type locality on December 31, 1963, at an elevation of about 15 m., by S. L. Wood.

The holotype and paratypes are in my collection.

Scolytodes (s. str.) venustus, n. sp.

Closely related to pseudopiceus, described below, but the female frons more finely punctured with the pubescence more abundant and evenly distributed, and the striae not impressed, the punctures fine and shallow.

Female.—Length 1.6 mm. (paratypes 1.4-1.8 mm.), 2.8 times as long as wide; color very dark brown, almost black.

Frons flattened from upper level of eyes to epistoma (rather narrowly above); surface subreticulate and finely punctured above eyes, subshining and rather coarsely punctured on flattened area, a small, shining, impunctate, central area on lower half; epistomial lobe not evident; vestiture consisting of fine, sparse, moderately long hair.

Pronotum 1.0 times as long as wide; widest at base, sides of basal half almost straight and parallel, rather broadly rounded in front; entire surface reticulate, the punctures coarse, deep, rather close, becoming somewhat smaller in anterior area; not at all asperrate anteriorly; glabrous except apical sides.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae 1 rather strongly, others rather weakly impressed, the punctures moderately large, deep, very close; interstriae about one and one-half times as wide as striae, almost smooth, with a few fine points, the punctures more than half as large as those of striae, deep, rather close, unisetate. Declivity steep, convex; about as on disc, except all punctures smaller. Glabrous, except for sparse, short hair on sides and marginal areas behind.

Male.—Similar to female except frons convex, reticulate, finely, sparsely punctured, subglabrous; anterior fourth of pronotum finely asperrate, the punctures in this area obscured.

Type Locality.—Rodeo, Esquinta, Guatemala.

Host.—Plumeria sp. (type), P. rubra and Ficus sp. (paratypes).

Type Material.—The female holotype, male allotype, and 37 paratypes were collected at the type locality on June 4, 1961, at an elevation of about 200 m., by S. L. Wood, from branches of Plumeria; 11 paratypes bear identical data but were taken from Ficus branches; 30 also have identical data but were taken from an unidentified tree branch. Four paratypes were taken at Playa del Coco, Guanacaste Prov., Costa Rica, on July 11, 1966, at sea level, from Plumeria rubra. The beetles live in green phloem next to dying tissues or in recently cut branches. The complete life cycle can be completed in less than 20 days.

The holotype, allotype, and paratypes are in my collection.

Scolytodes (s. str.) pseudopiceus, n. sp.

Allied to cecropiavorus Wood, described above, but female frons devoid of frontal carinae, the anterior area of male pronotum feebly asperrate, almost smooth in female, the striae not impressed.

Female.—Length 1.7 mm. (paratypes 1.4-1.9 mm.), 2.4 times as long as wide; color very dark brown, almost black.

Frons flattened from just above upper level of eyes to epistoma, evidently feebly convex near center; rather coarsely, closely punctured; ornamented by a rather scanty brush of fine, long, hair, the distribution about uniform, except reduced or absent toward center.

Pronotum 1.04 times as long as wide; widest near base, the sides weakly arcuate, converging slightly to anterior third then rather narrowly rounded in front; summit indefinite, near middle; anterior third appearing weakly crenulate from above, but only feebly wrinkled from other aspects; surface subreticulate, rather coarsely, deeply, closely punctured from base to anterior margin; glabrous.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, the punctures rather fine, deep; interstriae more than twice as wide as striae, almost smooth, the punctures subequal to those of striae, in almost regular, unisetate rows. Declivity steep, convex; striae 1 slightly impressed; all punctures smaller than on disc. Glabrous.

Male.—Similar to female except frons convex, with a slight transverse impression just above epistomal margin, the surface reticulate and sparsely, rather deeply punctured.

Type Locality.—San Isidro del General, San José Prov., Costa Rica.

Host.—Ficus sp.

Type Material.—The female holotype, male allotype, and 17 paratypes were collected at the type locality on December 5, 1963, at an elevation
of 1,000 m., by S. L. Wood, from phloem tissues in a small twig less than 1 cm. in diameter. The beetles apparently attack and kill small green twigs on healthy trees.

The holotype, allotype, and paratypes are in my collection.

_Scolytodes (Hexacolus) ochromae_, n. sp.

The species is allied to _swieteniae_ (Blackman), although it is not closely related. It may be distinguished by interstriae 10 not extending behind level of metacoxae, by the interstriae being almost devoid of punctures and by the absence of a frontal carina.

**Female.**—Length 1.4 mm. (paratypes 1.3-1.5 mm.), 2.1 times as long as wide; color rather dark brown.

Frons almost flattened above to upper level of eyes, shallowly concave below, epistoma somewhat elevated; central area on upper half smooth, impunctate, remaining areas coarsely, densely, deeply punctured; lateral areas above antennal insertions and dorsal ornamented by a scanty tuft of long, yellow hair, a few scattered setae on lower third.

Pronotum 0.95 times as long as wide; widest at base, sides feebly arcuate and slightly converging anteriorly on basal two-thirds, then rather abruptly converging toward the very narrowly rounded anterior margin; summit indefinite, near middle; anterior three-fourths armed by broad, rather coarse crenulations; basal fourth subreticulate, shining; glabrous.

Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal half, obtusely angulate behind; striae 1 weakly, others not at all impressed, the punctures rather, coarse, shallow, the rows not entirely straight; interstriae almost twice as wide as striae, almost smooth, punctures not evident. Declivity steep, convex; striae punctures evidently smaller than on disc; occasional interstrial punctures obscurely indicated; apex turned very slightly posteriorly. Vestiture consisting of sparse flattened bristles, mostly on declivity, not more than about six or seven on any one interspace. Interspace 10 acutely elevated only to level of hind coxae.

**Male.**—Similar to female except frons convex above level of antennal insertions, transversely impressed between that level and epistomial process, sparsely punctured.

**Type Locality.**—Playon, San José Prov., Costa Rica.

**Host.**—_Ochroma velutina._

**Type Material.**—The female holotype, male allotype, and 37 paratypes were collected at the type locality on August 9, 1963, at an elevation of about 50 m., by S. L. Wood, from the bark of branches of a cut balsa tree. Little could be discerned of the habits except that eggs apparently were scattered indiscernimantly in the oval nuptial chamber.

The holotype, allotype, and paratypes are in my collection.

_Scolytodes (Hexacolus) cedrelae_, n. sp.

Very closely related to _swieteniae_ (Blackman), but the frontal carina does not attain the epistomial margin in either sex. The female carina (sometimes double) begins well above the epistoma; in addition, the female of this species has the lower frons more distinctly punctured and ornamented by sparse hair; the tuft of hair on the vertex also extends ventrad to a point in line with the anterior margin of the eye, this tuft in _swieteniae_ ends well above that point.

**Female.**—Length 1.5 mm. (paratypes 1.3-1.5 mm.), 2.2 times as long as wide; color yellowish brown, with anterior and posterior ends and elytral suture dark.

Frons flattened from vertex to epistoma; middle half between upper level of eyes bearing a low median carina of uniform height; epistomial margin and sides near antennal bases rather coarsely deeply punctured; vestiture consisting of a dense brush of long yellow hair on vertex extending downward laterally to anteronesal angle of eye; sparse hair scattered on lower area.

Pronotum 1.1 times as long as wide; sides subparallel on basal half, converging slightly to anterior fourth, then broadly rounded in front; summit indefinite, near middle; anterior half armed by numerous, close, shining, narrow crenulations; posterior half reticulate, dull, with very fine, obscure punctures, and in discal area with small, transverse, shining granules extending to base.

Elytra 1.2 times as long as wide, 1.1 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather narrowly rounded behind; striae not impressed, the punctures moderately large, shallow; interstriae almost twice as wide as striae, almost smooth, subshining, the punctures obscure, uniseriate. Declivity steep, convex; striae 1 and possibly 2 weakly impressed, the punctures of striae and interstriae small and deeper than on disc. Vestiture consisting of a few flattened bristles on alternate odd interspaces, mostly on declivity.

**Male.**—Similar to female except frons convex, with a weak transverse impression just above epistoma, the surface reticulate and sparsely punctured.

**Type Locality.**—Rincon de Osa, Puntarenas Prov., Costa Rica.

**Host.**—_Cedrela mexicana._

**Type Material.**—The female holotype, male allotype, and 61 paratypes were collected at the type locality on August 11, 1966, at an elevation of about 100 m., by S. L. Wood, from transverse tunnels in the phloem of large cut logs of the above host. Fragments of this species were also found in logs of two other unidentified host species.

The holotype, allotype, and paratypes are in my collection.

_Scolytodes (Hexacolus) immanis_, n. sp.

Allied to _alni_, described below, but larger, stouter, all striae punctures in rows, and the pronotal punctures smaller.
Female.—Length 3.5 mm. (paratype 3.5 mm.), 2.4 times as long as wide; color very dark brown on head, anterior half of pronotum, elytral suture and under parts, light yellowish brown on posterior half of pronotum, elytra and legs.

Frons flattened from well above upper level of eyes to epistoma with median third of lower half very feebly impressed; impressed area smooth, shining, remaining lateral and dorsal areas rather coarsely, closely, shallowly punctured; vestiture consisting of coarse, long, subpulv

Pronotum 1.04 times as long as wide; sides almost straight and parallel on basal two-fifths, then arcurately converging to the rather narrowly rounded anterior margin; dorsal profile arched from base to anterior margin, the indefinite summit on basal half; minutely, closely asperate in front of summit, reticulate and minutely, rather obscurely punctured behind, glabrous except for a few small setae at anterolateral angles.

Elytra 1.5 times as long as wide, 1.9 times as long as pronotum; sides almost straight, widest near base of declivity, narrowly rounded behind; striae not impressed, the punctures fine, shallow, in definite rows; interstria three times as wide as striae, almost smooth, the punctures smaller than those of striae, shallow, rather numerous, confused. Declivity convex, rather steep; striae 1 and perhaps interspace 2 weakly impressed on middle third. Glabrous.

Male.—Not represented in the series at hand.

Type Locality.—Villa Mills near Cerro de la Muerte, Cartago Prov., Costa Rica.

Host.—Alnus acuminata.

Type Material.—The female holotype and one female allotype were collected at the type locality on June 28, 1963, at an elevation of 2,300 m., by S. L. Wood, from irregular tunnels in the phloem tissues in stumps of the above host. Seventeen additional paratypes bear identical data, but were taken on October 26, 1963.

The holotype, allotype, and paratypes are in my collection.

Scolytyodes (Hexacolus) erineophilus, n. sp.

Allied to marginatus, described below, but the relationship is not close. It is distinguished by the stouter pronotum with the anterior margin unarm'd, and by the flattened female frons with the central area glabrous.

Female.—Length 1.6 mm. (paratypes 1.4-1.6 mm.), 2.4 times as long as wide; color medium brown.

Frons feebly convex, almost flat, on a rather narrow area from just below upper level of eyes to epistomal margin; surface etched by minute, transverse lines in central half of flattened area, remainder of flattened area rather coarsely, not closely punctured; convex area above reticulate, with sparse, fine punctures; vestiture consisting of sparse, fine, long hair on punctured part of flattened area, not conspicuous.

Pronotum 1.9 times as long as wide; widest at base, the sides very feebly aruncate, almost straight, and converging anteriorly, then rather strongly, not abruptly rounded to the broadly rounded anterior margin; finely, closely asperate on anterior half, the asperities decreasing in size and density behind, continued as very fine transverse granules to basal fourth; posterior surface and spaces between asperities strongly reticulate, finely, rather sparsely punctured behind, the anterior rims of punctures granulate except on basal fourth. Vestiture sparse, inconspicuous, confined to anterior and lateral areas.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, the punctures small, distinct, rather deep; interstriae about one and one-half times as wide as striae, subshining, the punctures about two-thirds as large as those of striae, unisieriate. Declivity moderately steep, convex; stria and interstrial punctures greatly reduced in depth and clarity, obscure. Vestiture rather abundant, consisting of short, fine, semirecumbent stria and interstrial hair, intersetial setae on and near declivity longer, erect, stout, somewhat flattened.

Male.—Similar to female except from weakly convex, reticulate, finely, sparsely punctured, the frontal vestiture shorter, less abundant; a few scattered, erect, interstrial bristles on interspaces 1, 3, and 5 almost to elytral base.
Type Locality.—Tapanti, Cartago Prov., Costa Rica.

Host.—Ficus sp.

Type Material.—The female holotype, male allotype, and 20 paratypes were collected at the type locality on August 17, 1963, at an elevation of 1.300 m., by S. L. Wood, from the phloem of twigs less than 1 cm. in diameter of a native fig tree.

The holotype, allotype, and paratypes are in my collection.

Scolytodes (Hexacolus) marginatus, n. sp.

Although the relationship may be superficial, this species appears rather closely allied to impressus (described below) but it is easily distinguished by the posteriorly extended tenth eyletal interspace, by the finer vestiture, and by the general sculpture.

Female.—Length 1.6 mm. (paratypes 1.5-1.7 mm.), 2.9 times as long as wide; body color rather light brown.

Frons broadly plano-convex from upper level of eyes to epistoma, a shining median carina beginning as a fine line near center, becoming broader and somewhat higher then ending abruptly just above epistomal margin surface reticulate, finely, sparsely punctured, the punctures larger and deeper near margins of flattened area; vestiture confined to marginal areas, consisting of fine, rather abundant, moderately long hair.

Pronotum 1.2 times as long as wide; sides straight and parallel on basal two-thirds, evenly, rather broadly rounded in front; anterior margin armed by ten teeth; strongly declivous and asperate on anterior third, the asperities rather large and broad, many of them arranged in broken subconcentric rows; posterior area reticulate, rather coarsely, closely punctured; vestiture confined to asperate and lateral areas, disc glabrous.

Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; striae narrowly impressed, the punctures small, shallow, interstriae about one and one-half times as wide as striae, moderately convex, smooth, the punctures small, rather sparse, some minutely subvilpicate, uniseriate. Declivity steep, convex; striae 1 rather strongly impressed, others less strongly impressed than on disc; strial and interstrial punctures somewhat finer; interspace 1 slightly elevated. Vestiture consisting of fine, erect, rather long, interstitial hair.

Anterior coxae subcontiguous.

Male.—Similar to female except frons broadly convex, coarsely, closely, deeply punctured, with a smooth, shining, slightly elevated callus on lateral fourth of epistomal margin; elytral vestiture consisting of apically flattened bristles.

Type Locality.—Dominical, Puntarenas Prov., Costa Rica.

Type Material.—The female holotype, male allotype, and 8 paratypes were collected at the type locality on December 9, 1963, at sea level, from the phloem of small twigs in a large tree.

The holotype, allotype, and paratypes are in my collection.

Scolytodes (Hexacolus) plicatus, n. sp.

The armed anterior pronotal margin indicates a relationship to impressus and marginatus, both described in this article. It is unique among Costa Rican species in the remarkably broad pronotal asperities, some of which may equal one-fifth of the total width of the pronotum.

Female.—Length 1.6 mm. (paratypes 1.5-1.8 mm.), 2.5 times as long as wide; color rather light brown.

Frons mostly convex, subconcavely impressed on central third, a broad, shining callus surrounding lower third of impression; surface rather finely punctured at sides and above to level well above upper level of eyes; vestiture fine, hairlike, moderately long and abundant on punctured area.

Pronotum 1.1 times as long as wide; widest at base, sides almost straight on posterior two-thirds, converging slightly anteriorly, broadly rounded in front; anterior third rather strongly declivous, the asperities rather low, sharply raised, very broad, some as much as a fourth the total width of pronotum; anterior margin armed by a continuous costa; posterior half reticulate, with fine, shallow punctures; glabrous except for a few bristles on anterior margin.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; striae 1 weakly, others not impressed, the punctures small, shallow, not sharply defined; interstriae subreticulate, almost twice as wide as striae, the punctures fine, shallow. Declivity convex, moderately steep; striae 1 narrowly impressed; all punctures smaller and somewhat deeper than on disc. Vestiture consisting of a few sparse, erect, declival hairs on odd numbered interspaces.

Male.—Similar to female except frons convex, reticulate, with a few obscure punctures, subglabrous.

Type Locality.—Twenty-five km. southeast of Guapiles, Limón Prov., Costa Rica.

Host.—Ficus sp.

Type Material.—The female holotype, male allotype, and 8 paratypes were collected at the type locality on August 22, 1966, at an elevation of about 100 m., by S. L. Wood, from the phloem of the bole of a large, cut, native, fig tree.

The holotype, allotype, and paratypes are in my collection.

Scolytodes (Hexacolus) pubescens, n. sp.

This species is readily distinguished from other Central American species by the armed anterior pronotal margin and other characters, however, it does not appear to be closely allied to any of them. The punctuation and vestiture of the elytral declivity and the sculpture of the female frons serve to distinguish it.

Female.—Length 1.8 mm. (paratypes 1.5-1.8 mm.), 2.4 times as long as wide; color rather dark brown, elytra and basal half of pronotum lighter.

Frons subconcavely impressed on slightly more than median half, with a pair of shining, rather strongly elevated, longitudinal carinae at lateral margins of cavity; surface of entire frontal area except carinae
Brigham Young University Science Bulletin

finely, closely punctate-granulate; vestiture consisting of rather coarse, moderately long setae, rather sparse in concave area, rather dense lateral to carinae and continuing above to a level slightly above upper level of eyes, not longer above.

Pronotum 1.1 times as long as wide; widest at base, the sides very weakly arcuate on basal two-thirds, rather narrowly rounded in front; rather coarsely asperate on anterior half, the asperities confused; anterior margin armed by about a dozen low teeth; posterior half shining, coarsely, closely, deeply punctured. Vestiture hairlike, moderately abundant except glabrous at center of disc.

Elytra 1.3 times as long as wide, 1.2 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae feebly if at all impressed, the punctures close, moderately large, deep; interstriae slightly wider than striae, shining, the punctures close, almost as large and as deep as those of striae. Declivity convex, steep; all punctures smaller than on disc, confused lateral to striae 2. Vestiture rather abundant, consisting of erect, short, strial hair and slightly longer interstrial hair; not conspicuously longer on declivity.

Male.—Similar to female except frons convex, reticulate, obscurely punctured, with sparse, inconsiderable, fine hair; elytral vestiture coarser and evidently more abundant.

Type Locality.—San Ignacio de Acosta, San José Prov., Costa Rica.

Type Material.—The female holotype, male allotype, and 33 paratypes were collected at the type locality on July 5, 1963, at an elevation of 1,100 m., by S. L. Wood, from phloem tissues of a new fern post taken from an undetermined tree species.

The holotype, allotype, and paratypes are in my collection.

Habits.—Except for the nuptial chamber that reached the cambium region, the tunnels of this species were confined to the region where the inner and outer bark meet. The system of parent tunnels was roughly star-shaped, with the egg tunnels tending to be transverse. About two or three females were associated with each male. They were associated with Scolytus dimidiatus.

Scolytodes (Hexacolus) impressus, n. sp.

This species is rather closely allied to marginitus Wood, described above, but is easily distinguished by the shortened elytral interspace 10, by the more finely punctured male frons, by the suppression of reticulation on the posterior half of the pronotum, by the coarser strial punctures, and by the more abundant elytral bristles.

Male.—Length 1.5 mm. (paratypes 1.3-1.7 mm.), 2.6 times as long as wide; color rather dark, reddish brown.

Frons convex except transversely impressed along epistoma; surface obscurely reticulate, subshining, with rather fine, sparse, sharp punctures except close and deep along epistoma; vestiture largely confined to epistoma.

Pronotum 1.2 times as long as wide; sides straight and parallel on basal two-thirds, rather broadly rounded in front; anterior third finely, closely asperate; posterior half subshining, obscurely reticulate toward indefinite summit, a few minute points present, the punctures coarse, close, deep, separated by less than the diameter of a puncture; vestiture obscure, on asperate and lateral areas.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae 1 moderately, others weakly impressed, the punctures coarse, deep, interstriae as wide as striae, shining, the punctures fine, some indistinct, uniserate. Declivity convex, steep; striae, particularly 1, more strongly impressed than on disc; interspace 1 slightly elevated; the punctures not reduced in size; vestiture consisting of apically flattened, interstitial bristles on disc and declivity, the distance between rows and between bristles in a row about equal to length of a bristle.

Female.—Not represented in the material at hand.

Type Locality.—Turrialba, Cartago Prov., Costa Rica.

Type Material.—The male holotype and 28 male paratypes were collected at the type locality on March 3, 1964, at an elevation of about 600 m., by S. L. Wood, from phloem tissues of an unidentified broken limb.

The holotype and paratypes are in my collection.

Scolytodes (Hexacolus) exiguis, n. sp.

By definition this species should be placed in the subgenus Hexacolus due to the pronotal asperities and absence of punctures toward the anterior margin of the pronotum; however, it almost certainly is more closely related to species here placed in the subgenus Scolytodes (s. str.). Its uniformly arched pronotum, pronotal sculpture, elevated declival interspace 9, and other characters serve to distinguish it.

Male.—Length 1.2 mm. (paratype 1.3 mm.), 2.0 times as long as wide; color very dark brown.

Frons convex, becoming somewhat flattened toward epistoma; surface shining, with small, sparse punctures above, more coarsely punctured below except on shining lateral margins below level of antennal insertion; vestiture very sparse except along epistomal margin.

Pronotum 1.0 times as long as wide; widest at base, sides feebly arcuate and converging on basal two-thirds, rather broadly rounded in front; dorsal profile arched from base, but more strongly declivous on anterior third; finely asperate on anterior third, punctures intermixed with asperities to anterior tenth but evidently not attaining anterior margin; posterior area shining, with very indistinct suggestion of reticulation and a few minute points, the punctures rather coarse, close, deep, separated by distances about equal to their diameters; vestiture consisting of a few bristles in asperate area.

Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal half then increasingly arcuate to the rather narrowly rounded posterior margin; basal margins marked by a
fine raised line; striae not impressed, the punctures rather large, moderately deep; interstriae about as wide as striae, shining, almost smooth, the punctures fine, shallow, uniseriate. Declivity convex, moderately steep; striae moderately to weakly impressed, the punctures somewhat smaller than on disc, deep; interstriae 1 weakly elevated, 2 and 3 weakly convex, the punctures about as on disc. Vestiture consisting of erect, apically flattened, interstitial bristles of moderate length, abraded on disc of type but on both disc and declivity of paratype.

Female.—Not represented in the material at hand.

Type Locality.—San Isidro del General, San José Prov., Costa Rica.

Host.—Ficus sp.

Type Material.—The male holotype and one male paratype were taken at the type locality on December 5, 1963, at an elevation of 1,000 m., by S. L. Wood, from phloem tissues of a small twig of Ficus.

The holotype and paratype are in my collection.

*Scolytodes (Hexacolus) pumilus*, n. sp.

Not related to any species of this genus known to me. Interstriae 10 ends before level of metacoxae, the pronotum is equal in width and length, the slender body is 2.5 times as long as wide, and there are a few minute asperities on anterior third of the pronotum.

Female.—Length 1.5 mm. (paratypes 1.4-1.6 mm.), 2.5 times as long as wide; color rather dark brown.

Frons rather narrowly flattened from just below upper level of eyes to epistoma; surface finely reticulate-granulate, the moderately large punctures rather close, only slightly less dense at center; vestiture very fine, moderately dense, rather long.

Pronotum 1.0 times as long as wide; widest at base, converging slightly on basal two-thirds, rather broadly rounded in front; dorsal profile arched from base, more strongly declivous on anterior third; asperities small, confined; posterior area reticulate, with very fine, sparse punctures; glabrous.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly, evenly rounded behind; striae not impressed, the punctures rather coarse, deep; interstriae almost smooth, about as wide as striae, the punctures indefinite or absent on basal half, small, uniseriate, becoming distinct toward declivity. Declivity rather steep, narrowly convex, striae 1 weakly impressed; striae punctures smaller than on disc, deep; interstriae shining, the punctures rather small, deep. Glabrous.

Male.—Similar to female except frons rather weakly convex, surface almost smooth and shining, reticulation obscurely indicated, the punctures minute, obscure; striae somewhat confused on basal fourth, interstrial punctures more evident on 1 and 2.

Type Locality.—Volcan Poas, Heredia Prov., Costa Rica.

Hosts.—*Conostegia oerstediana*, Drimys granadensis and *Sapium thelocarpum* (paratypes).

Type Material.—The female holotype, male allotype, and 12 paratypes were collected just below the summit (about 100 m. below) of Volcan Poas, on August 19, 1966, by S. L. Wood, from phloem tissues of an unidentified broken tree branch. The following additional paratypes were also taken in Costa Rica during 1963, by S. L. Wood: 22 from 10 km. southeast of Cartago, Cartago Prov., July 3, at 1,800 m., from the above species of *Conostegia* and *Drimys*; and 24 from the type locality on July 14, from the above species of *Sapium*.

The holotype, allotype, and paratypes are in my collection.

*Pseudothyssanae acacicolens*, n. sp.

This species is closely allied to *spinatus* Wood, but is readily distinguished in the male by the much smaller declival spines, by the unaltered sculpture and vestiture of the elytral declivity, both are essentially continuous with that of the disc. In the female the pronotum is more coarsely reticulate and the elytral declivity more coarsely punctured than in *spinatus*, evidently with very fine granules on interspace 3.

Male.—Length 1.1 mm. (male paratypes 1.0-1.2; female paratypes 1.1-1.3 mm.), 2.4 times as long as wide; color light brown.

Frons convex above, transversely impressed above epistoma; surface coarsely reticulate; vestiture consisting of scattered, rather short, subplumose hair.

Pronotum 1.0 times as long as wide; subcircular, with a slight constriction on anterior half; anterior margin armed by six irregular teeth; summit at middle, high; coarsely asperate in front; posterior area rather coarsely reticulate, the punctures fine, inoposnicious; vestiture rather abundant, consisting of suberect slender scales and shorter hair intermixed.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly, evenly rounded behind; striae not impressed, the punctures moderately large, rather deep; interstriae as wide as striae, 1 and to a lesser extent 5 bearing a uniseriate row of moderately large, low tubercles, the punctures on other interspaces weakly if at all granulate. Declivity convex, very slightly flattened on upper half; striae as on disc but evidently somewhat narrower; interspace 2 bearing a slender spine at upper margin of declivity, and a similar spine one-fourth of declival length from upper margin; the spines similar in position and shape to those of *spinatus* but only half as long; interspace 5 bearing two similar but smaller spines, one just above and one just below level of lower spine on interspace 2; granules on 2 and 5 not continued below lower spine on each interspace. Vestiture consisting of fine strial hair and interstrial scales; each scale about four times as long as wide on disc and sides, somewhat shorter on striae 1.3 on lower two-thirds of declivity.

Female.—Similar to male except larger, more slender; frons a little less strongly convex; anterior margin of pronotum unarmed; declivity more strongly convex, unarmed; elytral scales more slender, somewhat shorter and narrower on declivity.

Type Locality.—Playa del Coco, Guanacaste Prov., Costa Rica.

Host.—*Acacia* sp.
Type Material.—The male holotype, female allotype, and 66 paratypes were collected at the type locality on March 21, 1967, at 10 m. elevation, by S. L. Wood, from the bank of the above host (spines slender).

Pseudothysanoes vallatus, n. sp.

This remarkable species is entirely unique in the genus. Presumably it is allied to *lecontei* Blackman, but the male declivital interstriae 3 are exceedingly strongly elevated and very coarse serrate, the height of the elevation exceeds the combined widths of interstriae 1 and 2, 1 is neither elevated nor serrate, the elevation is only moderately developed, in the female.

Male.—Length 1.1 mm. (female paratypes 1.013 mm.), 2.7 times as long as wide; color very dark brown.

Frons convex, a slight transverse impression just above epistoma; surface rather coarsely reticulate except almost smooth on epistomal area; vestiture rather sparse, moderately long, consisting of subglomose setae. Scape short, only slightly longer but distinctly wider than pedicel, club small, oval, two weakly arcuate sutures indicated by setae.

Pronotum subcircular in outline, anterior margin armed by two subcontiguous teeth; anterior slope asperate, summit at middle; posterior area transversely subtrigose-reticulate with a few very small granules, more regularly reticulate laterally; vestiture consisting of rather sparse, slender scales and hair of equal length intermixed.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then rounded to meet broadly truncate apex; striae not impressed, the punctures small, distinct; interstriae slightly narrower than striae, each bearing a uniseriate row of small, rounded squamiferous granules. Declivity rather steep; flattened to weakly excavated between the very strongly, very narrowly elevated interstriae 3, 1 feebly elevated toward apex, the punctures of striae 1 and 2 more strongly impressed than on disc; interstriae 3 elevated to sutural apex, armored by 10 very coarse, contiguous, blunt teeth that increase in size to just below middle of declivity; interstriae 1-9 each bearing one to three rounded nodules at base of declivity, those on 7 largest. Vestiture consisting of rows of interstrial scales and smaller striaal hair; the scales longer on declivity, particularly those on summit of elevated crest of interstriae 3.

Female.—Similar to male except frons weakly impressed to upper level of eyes and more finely sculptured; scape slightly larger and bearing a small tuft of hair; anterior margin of pronotum unarmed; declivital interstriae 3 only moderately elevated and unarmed, the nodules at base of declivity also absent.

Type Locality.—Volcan Colima, Jalisco, Mexico.

Host.—*Struthanthus venetus*.

Type Material.—The male holotype, female allotype, and 12 female paratypes were taken at the type locality on June 23, 1965, 2,500 m., No. 105, from the above host, by S. L. Wood. The specimens were intermixed with *Micracisella* and another *Pseudothysanoes*. It is presumed they mined in the cambium region.

The holotype, allotype, and paratypes are in my collection.

Pseudothysanoes vesicus, n. sp.

This species is closely related to *helitara* Wood, but it is easily distinguished by the smaller size, by the more slender form, by the non-elevated apical margin of the male declivity, and by the excavated female frons that bears a tuft of minute setae toward the vertex.

Male.—Length 1.1 mm. (female paratypes 0.911 mm.), 2.4 times as long as wide, color brown.

Frons not visible. Antennal scape long; sutures on club largely obsolete.

Pronotum 0.97 times as long as wide; widest near base, sides weakly arcuate, converging slightly before the broadly rounded, unarmed anterior margin; summit distinct, asperate on anterior slope, subshining, minutely, obscurely punctured and with obscure lines behind; vestiture with scales and short stout hair intermixed.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides straight, increasing very slightly posteriorly to obliquely truncate declivity; striae not impressed the punctures distinctly impressed; interstriae wider than striae, the punctures uniseriate, fine, obscure. Declivity obliquely truncate, the face evenly, weakly convex, an acutely elevated ridge extending from suture above around margin of declivity about three-fourths the distance to sutural apex, obsolete on this final fourth; striaal and interstrial punctures equal in size, very close, moderately deep over entire face. Vestiture consisting of rows of interstrial scales and short striaal hair; scales on disc about three times as long as wide, increasing slightly in length toward declivity; declivital margin bearing a ring of closely set, much larger, stout scales; scales on declivital face uniform in size, much smaller and more slender than on disc.

Female.—Similar to male except frons shallowly, broadly concave from epistoma to vertex, the median third of upper half densely pilose; striaal punctures finer; declivity convex, without elevated margin, the sculpture essentially as on disc but slightly deeper; vestiture as on disc and somewhat finer.

Type Locality.—Three km. west of Armeria, Colima, Mexico.

Type Material.—The male holotype, female allotype, and four female paratypes were collected on June 28, 1965, 70 m., No. 131, by S. L. Wood, from a branch of an unidentified thorn tree.

The holotype, allotype, and paratypes are in my collection.

Pseudothysanoes mensus, n. sp.

This species is very closely related to *spinura* Wood, but it is distinguished in the male by the steeper elytral declivity, with the circumdeclivital elevated costa higher and more acute particularly on the upper half, and, in the female, by the very deeply excavated frons.
Male.—Length 1.0 mm. (paratypes 1.0-1.2 mm.). 2.4 times as long as wide; color dark brown.

Frons as in spinus with a slightly broader impression. Pronotum 0.97 times as long as wide, otherwise as in spinus.

Elytra evidently 1.5 times as long as wide, as in spinus except declivity slightly steeper, the circum-decital costa more strongly subacutely elevated from sutural margin above to sutural margin below; spine-like setae on declival interspaces 1 in number and at least as long as vestiture similar.

Female.—As in the female of spinus except frons very deeply excavated on median three-fourths from epistoma to vertex, the deepest point at upper level of eyes; general surface of elytral declivity more irregular.

Type Locality.—Three km. east of Armeria, Colima, Mexico.

Type Material.—The male holotype, female allotype, and 34 paratypes were collected at the type locality on June 28, 1965, 70 m., No. 131, by S. L. Wood from the cut limb of an unidentified thorn tree. The tunnels were in the cambium region.

The holotype, allotype, and paratypes are in my collection.

_Pseudothysanos visicurus_, n. sp.

This species is closely allied to _phorodendron_ Blackman, but it may be distinguished by the larger size, by the deeper, coarser male strial punctures, by the more broadly rounded male declivity, and by the larger interstitial granules on the disc.

Male.—Length 1.7 mm. (paratypes 1.4-1.7 mm.), 2.3 times as long as wide; color dark brown to black, summit of pronotum reddish.

Frons convex, transversely impressed on lower half, subconverse toward center; surface finely reticulate-granulate, with small, obscure punctures; vestiture of sparse, subplumose setae of moderate length.

Pronotum 0.9 times as long as wide; widest on basal third, sides strongly arcuate on basal half, strongly constricted one-third length from the narrowly rounded anterior margin; margin armed by six small teeth; summit behind middle, well developed; anterior slope coarsely asperate to summit; posterior area coarsely reticulate, the fine punctures obscure; vestiture of intermixed fine hair and slightly longer, erect scales, each scale about four to six times as long as wide.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae very weakly impressed toward declivity, the punctures rather coarse, deep; interstitial as wide as striae, the punctures uniseriate, rather coarse, subgranulate on anterior margins especially toward declivity. Declivity beginning slightly in front of middle, moderately steep, broadly convex; striae weakly impressed, the punctures slightly larger than on disc; interstitial punctures usually not at all granulate. Vestiture consisting of minute strial hair and rows of interstitial scales; each scale on disc slightly shorter than distance between rows, each about three to four times as long as wide; scales on declivity equal in width to those on disc, but three times as long; scales on declival interstriae 8 and 9 in partial double rows and equal in length to one another.

Female.—Similar to male except anterior margin of pronotum unarm; elytra 1.5 times as long as wide, the declivity restricted to posterior third, more narrowly rounded and steeper; strial punctures smaller, similar on disc and declivity; interstitial granules larger and more regular; declival vestiture only slightly longer than on disc, each declival scale about four to six times as long as wide.

Type Locality.—Volcan Ceboorucu, Nayarit, Mexico.

Host._—Phoradendron probably robinsonii._

_Type Material._—The male holotype, female allotype, and 17 paratypes were collected at the type locality on July 5, 1965, about 1,100 m., No. 191, by S. L. Wood, from phloem galleries in branches of the above mistletoe.

The holotype, allotype, and paratypes are in my collection.

_Pseudothysanos amasonis_, n. sp.

This species is distinguished, with some difficulty, from _viscivorus_ Wood, described above, and it eventually may become a subspecies. It is distinguished by a slightly more strongly impressed frons, by the shorter, uniseriate scales on the male declival interspace 9 and a reduced number of scales on 8, and by the much broader interstitial scales of the female.

Male.—Length 1.5 mm. (paratypes 1.3-1.6 mm.), 2.1 times as long as wide; color dark brown to black, summit of pronotum reddish.

As in _viscivorus_ except frons more broadly, more deeply impressed; strial punctures near declivity somewhat finer, interstitial granules finer; scales on declival interstriae 9 uniseriate and distinctly shorter than those on 8.

Female.—As in the female of _viscivorus_ except frons more broadly, more strongly impressed; interstitial granules much smaller; interstitial scales much broader, each about two to two and one-half times as long as wide.

Type Locality.—Twenty km. south of Matias Romero, Oaxaca, Mexico.

Host._—Phoradendron sp._

_Type Material._—The male holotype, female allotype, and 10 paratypes were collected at the type locality on June 24, 1967, near 700 m., No. 93, by S. L. Wood, from tunnels in the phloem of a common mistletoe that awaits identification.

The holotype, allotype, and paratypes are in my collection.

_Pseudothysanos visicolens_, n. sp.

This species clearly is allied to _viscivorus_ Wood, but it is easily distinguished by the broader elytral scales which decrease in length on the lower half of the declivity, by the broadly concave female frons that bears a fringe of moderately long, yellow hair on the upper margin, and by the reduced female strial punctures.
Male.—Length 1.3 mm. (paratypes 1.3-1.7 mm.). 2.2 times as long as wide; color dark brown to black, pronotal summit reddish.

Frons (partly concealed in type) convex with a feeble impression above epistoma; an obscure subovate impression indicated near center; reticulate below, becoming minutely subgranulate above; vestiture sparse, inconspicuous.

Pronotum 0.92 times as long as wide; sides weakly arcuate, converging very slightly on basal two-thirds then broadly rounded in front; anterior margin armed by six small teeth; summit well developed; posterior area minutely rugulate, with sparse, small, subgranulate punctures; vestiture consisting of rather sparse, small, scale- and hair-like setae.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, the punctures rather small, deep; interstriae wider than striae, the punctures small, uniseriate. Declivity beginning well before middle of elytra, moderately steep, broadly convex; sutural striae only feebly impressed, the punctures distinctly larger and deeper than on disc; interstriae narrower, otherwise as on disc. Vestiture consisting of minute strial hair, and rows of erect interstrial scales; each scale on disc about twice as long as wide, about two-thirds as long as distance between rows; each scale on declivity as wide or slightly wider than those on disc and on upper half at least three times longer than those on disc, decreasing in length on interstriae 1 and 2 on lower half to size of scales on disc.

Female.—Similar to male except frons rather deeply concave from epistoma to vertex, the concavity clothed with moderately abundant, short, stout setae; the upper margin bearing a tuft of long yellow hair equal in length to half diameter of concavity; anterior margin of pronotum unarmed; declivity confined to posterior third of elytra; striae punctures somewhat reduced; interstrial granules small, regularly placed on disc and declivity; declivity more narrowly convex, the sculpture and vestiture as on disc, each scale three to four times as long as wide.

Type Locality.—Zamorano, Morazan, Honduras.

Host.—Phoradendron robustissimum.

Type Material.—The male holotype, female allotype, and 14 paratypes were collected at the type locality on April 18, 1964, 700 m., No. 569, by S. L. Wood, from tunnels in the phloem of the above-named mistletoe.

The holotype, allotype, and paratypes are in my collection.

Pseudothysanoes furvus, n. sp.

Among previously described species this one is more similar to phoradendri Blackman than to any other. It may be distinguished by the smaller size, by the more strongly convex, less strongly tuberculate elytral declivity and, in the male, by the much shorter, wider bristles on the elytral declivity.

Male.—Length 1.25 mm. (paratypes: males 1.1-1.3, females 1.2-1.4 mm.). 2.2 times as long as wide; color black with white scales.

Frons convex above, transversely impressed from just above level of antennal bases to epistomal margin; surface finely granulate; vestiture consisting of moderately abundant, coarse, short, subplumose hair.

Pronotum 0.93 times as long as wide; widest about one-third from base, sides rather strongly arcuate on basal half, laterally constricted on anterior half, narrowly rounded in front; anterior margin armed by eight striae that decrease in size laterally; summit just behind middle, rather high; coarsely asperate from summit forward; posterior area minutely punctulate-subgranulate and with obscure, fine punctures, more nearly reticulate laterally; vestiture of minute hair and longer, broad scales, those on asperate area longer.

Elytra 1.3 times as long as wide; 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, the punctures small, deep; interstriae almost twice as wide as striae, minutely irregular, the subcubital, squamiforous punctures low, almost as large as those of striae. Declivity convex, steep; sculpture about as on disc but punctures and granules somewhat smaller. Vestiture consisting of interstrial rows of erect scales; each scale as long as distance between rows and between adjacent scales in the same row, about three times as long as wide.

Female.—Similar to male except slightly larger, more slender, 2.8 times as long as wide; frons less coarsely sculptured, the vestiture more abundant, finer; antennal scape bearing a small tuft of subplumose hair; sculpture of pronotum finer, the anterior margin unarmed; elytral punctures and granules greatly reduced except only slightly recided on declivity; elytral scales smaller.

Type Locality.—Finca La Pacifica, Canas, Guanacaste Prov., Costa Rica.

Host.—Phoradendron sp.

Type Material.—The male holotype, female allotype, and 28 paratypes were collected at the type locality on April 13, 1966, at an elevation of about 50 m., by S. L. Wood, from stems of a mistletoe that grew in an unidentifiable cut tree. Forty-two additional paratypes were taken 20 km. southeast of Liberia on the Pan-American Highway, Guanacaste Prov., Costa Rica, on July 10, 1966, by S. L. Wood, from apparently the same species of mistletoe that grew in oak trees. A series not included in the type series was also collected at Zamorano, Morazan, Honduras, on April 18, 1964, at 700 m., by S. L. Wood, from Phoradendron robustissimum.

The holotype, allotype, and paratypes are in my collection.

Pseudothysanoes furvatus, n. sp.

This species is very closely related to furvus Wood, described above, but it may be distinguished by the much coarser and deeper male striae punctures, this difference only slight in the female, by the larger, closer, interstrial granules on the male disc, and by the slightly longer, more slender male declival scales, the female declival scales are more slender but slightly shorter.
Male.—Length 1.2 mm. (paratypes 1.0-1.4 mm.), 2.3 times as long as wide; color dark brown to black, with summit of pronotum reddish.

Frons and pronotum as in furvis.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, the punctures moderately large, deep; interstriae slightly narrower than striae, smooth, each with a uniseriate row of rather small, rounded, squamiferous granules, each granule as wide as interstriae. Declivity beginning at or just behind middle, rather steep, convex; sculpture as on disc except granules smaller, many obscure. Vestiture consisting of rows of erect interstrial scales, each scale on disc two to three times as long as wide, each equal in length at base to two-thirds distance between rows, equal to distance between rows at base of declivity; each scale on declivity about four to six times as long as wide and slightly longer than distance between rows.

Female.—As in female of furvis except as noted in the diagnosis above.

Type Locality.—Thirty-five km. north of Juchitlan, Jalisco, Mexico.

Host.—Phoradendron sp.

Type Material.—The male holotype, female allotype, and 31 paratypes were collected at the type locality on July 3, 1965, about 1,300 m., No. 183, by S. L. Wood, from tunnels in the phloem of a large mistletoe, awaiting identification, that grew in Juniperus deppeana. Thirteen additional paratypes were taken 42 km. southeast of Nochistlan, Oaxaca, Mexico, June 17, 1967, No. 55, by S. L. Wood, from Phoradendron sp.

The holotype, allotype, and paratypes are in my collection.

Pseudothyasnoes verdisus, n. sp.

This species is not closely related to any described species. The concave female frons that is ornamented by a tuft of long hair as in visciocolens Wood, described above, might suggest a relationship. This species differs from visciocolens by the more slender body form, by the elytral vestiture of the male resembling that of the female, and by the female frons being more broadly, evenly concave and ornamented by much longer setae.

Male.—Length 1.5 mm. (paratypes 1.3-1.8 mm.), 2.3 times as long as wide, color dark brown, pronotal summit reddish.

Frons convex above, moderately, transversely impressed just above epistoma with a slight impression toward center; surface finely, rugulose; vestiture sparse, rather short, widely distributed.

Pronotum 0.92 times as long as wide; widest at base, sides weakly arcuate and converging on basal three-fifths to a conspicuous constriction, rather narrowly rounded in front; anterior margin armed by four small teeth; summit rather high, behind middle; posterior area coarse-ly reticulate, with small, sparse, rounded, squamiferous granules; vestiture of intermixed fine, short hair and longer, slender scales.

Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, the punctures minute, distinct; interstriae about twice as wide as striae, irregularly marked by lines and obscure points, the punctures finely granulate, squamiferous. Declivity confined to posterior third, convex, rather steep; sculpture as on disc except granules smaller, obscure. Vestiture consisting of minute strial hair and rows of erect interstrial scales; each scale on declivity four to five times as long as wide, about equal in length to distance between rows, very slightly shorter on disc.

Female.—Similar to male except frons shallowly concave almost from eye to eye from epistoma to vertex, the upper margin ornamented by a dense tuft of long yellow hair reaching slightly beyond middle of concavity; scape with a small tuft of hair; anterior margin of pronotum unarmed; elytral scales slightly smaller.

Type Locality.—Seven km. north of Tlaxcala, Tlaxcala, Mexico.

Type Material.—The male holotype, female allotype, and 54 paratypes were collected at the type locality on June 6, 1967, 2700 m., No. 24, by S. L. Wood, from tunnels in the phloem of a large mistletoe, awaiting identification, that grew in Juniperus deppeana. Thirteen additional paratypes were taken 42 km. southeast of Nochistlan, Oaxaca, Mexico, June 17, 1967, No. 55, by S. L. Wood, from Phoradendron sp.

The holotype, allotype, and paratypes are in my collection.

Pseudothyasnoes junebris, n. sp.

This species is allied to verdisus Wood, described above, but it is distinguished by the much smaller concavity of the female frons and absence of the frontal tuft of hair, by the larger elytral granules, particularly in the male, and by the longer, more slender elytral bristles.

Male.—Length 1.4 mm. (paratypes 1.4-1.8 mm.) 2.4 times as long as wide; color black, summit of pronotum reddish.

Frons transversely impressed below upper level of eyes, the central area shallowly concave; finely granulate-punctate above eyes, finely punctured below; vestiture consisting of moderately abundant, subplumose setae of moderate length.

Pronotum 0.95 times as long as wide; outline and sculpture as in verdisus except granules in posterior area reduced and setae finer.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; outline as in verdisus; striae not impressed, the punctures moderately large, shallow, distinct; interstriae wider than striae, surface somewhat irregularly marked by lines, the punctures fine, uniseriate, becoming granulate near declivity. Declivity confined to posterior third, rather steep, convex; strial punctures greatly reduced above, obsolete below; interstriae 1 devoid of granules on lower three-fourths and 2 on lower half, upper half of 2, all of 3 and 4 and lateral areas armed by moderately large, somewhat pointed, isolated, squamiferous granules. Vestiture consisting of erect scales; each scale on disc about four times as long as wide, almost equal in length to distance between rows, more slender, one and one-half times as long and more widely spaced than on disc; spacing of scales within row on declivity slightly greater than spacing between rows.

Female.—Similar to male except frontal concavity slightly deeper and wider; anterior margin of pronotum
unarmed; elytra 1.7 times as long as wide, the surface somewhat more irregular; elytral declivity sculptured to apex as on disc; interstrial scales about six times as long as wide, not longer or more widely spaced on declivity.

**Type Locality.**—Twenty-seven km. west of Durango, Durango, Mexico.

**Host.**—Phoradendron villosum.

**Type Material.**—The male holotype, female allotype, and 41 paratypes were collected on June 4, 1965, about 2,000 m., No. 12, by S. L. Wood, from tunnels in the phloem of the above named mistletoe.

The holotype, allotype, and paratypes are in my collection.

**Pseudothysanoes peniculus**, n. sp.

This species is rather closely allied to *funebris* Wood, described above, but it is readily distinguished, in the male, by the continuation of all rows of interstrial scales to their normal termination on the declivity, and in the female, by the more extensively concave frons that is ornamented above by a very long tuft of yellow hair.

**Male.**—Length 1.4 mm. (paratypes 1.4-1.7 mm), 2.3 times as long as wide; color dark brown, part of elytra and summit of pronotum lighter in some specimens.

From rather strongly, broadly, transversely impressed on lower half, convex above, the epistoma gradually raised to margin; surface finely granulate-punctate, finer in impression; vestiture consisting of moderately abundant, short, subpublumose setae.

**Pronotum.** 0.96 times al long as wide; outline as in *verdicus*; surface behind summit rather coarsely reticulate, the minute, sparse punctures obscure; vestiture of scales and stout hair intermixed.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; outline as in *verdicus*; striae not impressed, the punctures small, shallow, obscure; interstriae about as wide as striae, irregularly marked, the punctures fine, obscure, very feebly granulate, squamiferous. Declivity on slightly more than posterior third, convex, moderately steep; sculpture essentially as on disc. Vestiture of rows of erect scales, each about four times as long as wide at base, at least eight times as long as wide on declivity, each slightly longer than distance between rows at base, increasing in length toward declivity until about twice as long as distance between rows on declivity, the spacing within each row equal to or slightly less than length of scale.

**Female.**—Similar to male except frons concave from eye to eye, from epistoma to vertex, area above eyes ornamented by a dense brush of long, yellow hair some of which extends to epistomal margin; scape with a rather large fringe of long hair; anterior margin of pronotum unarm ed; elytra 1.6 times as long as wide, declivity confined to posterior third; elytral surface, particularly on declivity, more nearly minutely rugulose; elytral scales shorter (about two-thirds as large) and closer.

**Type Material.**—Thirteen km. west of Texmelucan, Puebla, Mexico.

**Host.**—Phoradendron sp.

**Type Material.**—The male holotype, female allotype, and nine paratypes were collected at the type locality on June 13, 1967, 2,600 m., No. 26, by S. L. Wood, from tunnels in the phloem of the above mistletoe.

The holotype allotype, and paratypes are in my collection.

**Pseudothysanoes bullatus**, n. sp.

This species is rather closely allied to *peniculus* Wood, described above, but it is easily distinguished, in the male, by the presence of a rather large bulla on the lower half of declival interstriae 3 and by the broader elytral scales, and, in the female, by the shallowly concave frons with very short hair above.

**Male.**—Length 1.5 mm. (paratypes 1.5-2.0 mm), 2.3 times as long as wide; color very dark brown, posterior half of elytra usually lighter.

Frons moderately, transversely impressed on lower half, convex above; surface rather coarsely punctate-granulate above, finely rugulose on lower third; vestiture consisting of stout, rather sparse, short, subpublumose setae. Scape with about a dozen long setae.

**Pronotum.** 0.94 times as long as wide; widest at base, the sides aracutely converging from base to narrowly rounded anterior margin, with a slight constriction one-third from anterior margin; anterior margin armed by six small teeth; summit behind middle, well developed, broad; posterior area very finely rugulose-reticulate, the minute punctures obscure; vestiture of scales and hair intermixed.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; outline as in *verdicus*; striae not impressed, the punctures rather small distinctly impressed; interstriae wider than striae, minutely, irregularly marked by obscure lines and points, the squamiferous punctures rather fine, usually distinct, not granulate. Declivity occupying slightly more than posterior third, convex, rather steep; stria and interstrial punctures reduced, becoming obsolete by middle of declivity; points largely replace obscure lines on interstriae, the surface shining; interstriae 3 with a large, low bulla on upper part of lower half of declivity. Vestiture consisting of erect, interstrial scales, each about two to three times as long as wide, slightly longer toward declivity, those on upper declivity spaced within and between rows by a distance equal to length of a scale; lower two-thirds of declivity glabrous.

**Female.**—Similar to male except frons shallowly concave on median three-fourths from epistoma to above upper level of eyes, the upper area bearing rather numerous, moderately short, yellow setae; anterior margin of pronotum unarm ed and more broadly rounded; declival interstriae each bearing a uniseriate row of fine granules to apex, the bulla obscure; declivity shorter, steeper; vestiture more abundant, extending to apex, each scale more slender, about five times as long as wide.

**Type Locality.**—Forty-two km. southeast of Nochixtlán, Oaxaca, Mexico.

**Host.**—Phoradendron sp.

**Type Material.**—The male holotype, female allotype, and nine paratypes were collected at the type locality on June 17, 1967, about 2,300 m., No. 55, by S. L. Wood, from tunnels in the
phloem of the above mistletoe.

The holotype, allotype, and paratypes are in my collection.

_Pseudothysanoes plumalis_, n. sp.

This species evidently belongs to the _verdicus_ Wood, described above, group of species, although it is not closely related to any of those treated here. The female frons is feebly concave and not ornamented by long hair; the scape bears a large tuft of hair. The male elytral sculpture is simple and quite unlike related species.

_Male._—Length 1.4 mm. (paratypes 1.4-1.7 mm.), 2.4 times as long as wide; color dark brown.

Frons shallowly concave almost to upper level of eyes, convex above; surface rugose-reticulate with a few fine granules in convex area; vestiture sparse, inconspicuous. Scape with fewer than a dozen setae.

Pronotum 0.91 times as long as wide; outline as in _verdicus_; posterior area reticulate, the very fine punctures obscure; vestiture of fine and stout hairlike setae.

_Elytra_ 1.4 times as long as wide, 1.65 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, the punctures rather coarse, deep; interstriae narrower than striae, almost smooth, the punctures very fine, unsierate. Declivity largely confined to posterior third, convex, steep; striae greatly reduced, the interstrial punctures very finely granulate. Vestiture consisting of rows of small, erect, interstrial scales of about equal size on disc and declivity; each scale about three times as long as wide, about one-half as long as distance between rows of scales, spaced within rows by distances equal to about three times length of a scale.

_Female._—Similar to male except frons more broadly, somewhat more deeply concave; scape bearing a large, dense tuft of long, yellow hair; pronotum armed by two teeth on anterior margin; declivity slightly shorter and steeper; declival interstrial granules obsolete.

_Type Locality._—Eighteen km. north of Huaquapan, Oaxaca, Mexico.

_Type Material._—The male holotype, female allotype, and 10 paratypes were collected at the type locality on June 15, 1967, 2,000 m., No. 43, by S. L. Wood, from twigs in the cambium region in twigs of an unidentified tree.

The holotype and paratypes are in my collection.

_Pseudothysanoes coracinus_, n. sp.

This species is very similar to _hopkinsi_ Blackman, but it is not closely related. It is distinguished, in the male, by the more nearly flattened frons, by the more weakly impressed stria punctures, and by the much broader interstrial scales. The female remains unknown.

_Male._—Length 1.2 mm. (male paratypes 1.2-1.3 mm.), 2.2 times as long as wide; color almost black, pronotal summit reddish.

Frons convex above, weakly, transversely impressed just above epistoma, with a narrow impression extending dorsad to center of frons; surface rugulose-reticulate; vestiture sparse, consisting of coarse, subplumose setae of moderate length.

_Pronotum_ 0.84 times as long as wide; widest a third from base; sides rather strongly arcuate on basal two-thirds then weakly constricted before the rather broadly rounded anterior margin; anterior margin armed by four broad, low teeth; summit high, behind middle; posterior area reticulate, the punctures sparse, minute, obscure; vestiture of stout and slender, short, hairlike setae.

_Elytra_ 1.3 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather narrowly rounded behind; striae not impressed, the punctures rather small, distinct but not deep; interstriae about as wide as striae, the punctures unsierate, finely granulate. Declivity on slightly less than posterior half, convex, rather steep; as on disc except striae punctures slightly smaller, the interstrial granules very slightly higher. Vestiture consisting of minute, fine, strial hair and rows of erect interstrial scales; each scale about twice as long as wide; not longer on declivity.

_Type Locality._—Thirty-four km. north of Juchitlan, Jalisco, Mexico.

_Type Material._—The male holotype and three male paratypes were collected at the type locality on July 3, 1965, about 1,300 m., No. 182a, by S. L. Wood, from tunnels in the cambium region in twigs of an unidentified tree.

The holotype and paratypes are in my collection.

_Pseudothysanoes crassinis_, n. sp.

This species is allied to _hopkinsi_ Blackman, but it is not closely related. It is distinguished, in the male, by the much stouter body, by the longer, more slender interstrial scales, and by the large interstrial granules, and, in the female, by the slightly impressed frons, and by the much finer elytral sculpture and smaller scales.

_Male._—Length 0.9 mm. (paratypes: males 0.8-1.0 mm.; females 1.0-1.2 mm.), 2.0 times as long as wide; color black.

Frons and pronotum as in _coracinus_ (above) except teeth on anterior margin of pronotum more slender, the summit higher and wider, and the posterior areas obscurely reticulate.

_Elytra_ 1.1 times as long as wide, 1.25 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; striae not impressed, the punctures obsolete; interstriae each with a minute row of large tubercles, increasing in size toward declivity. Declivity beginning at middle, rather steep, convex; a few minute strial punctures obscurely indicated; interstrial granules greatly reduced on upper half, obsolete on lower half, replaced by very minute, obscure punctures. Vestiture consisting of fine, moderately long, suberect, strial hair and interstrial rows of longer, erect scales; each scale about four times as long as wide on disc, six times as long as wide on declivity; each scale as long as distance between rows on disc, slightly longer on declivity, spaced within rows by a slightly greater distance.

_Female._—Similar to male except larger; 2.4 times as long as wide; frontal impression very slightly larger; anterior margin of pronotum unarmed; stria punctures obscurely visible; interstrial granules obsolete; declivity
confined to posterior third of elytra, more narrowly convex; interstrial scales slender, at least eight times as long as wide.

**Type Locality.**—Twenty-four km. west of Tehuantepec, Oaxaca, Mexico.

**Type Material.**—The male holotype, female allotype, and 65 paratypes were collected from the type locality on June 22, 1967, 70 m., No. 35, by S. L. Wood, from tunnels in the cambium region in the bole of a small, thornless, leguminosae tree having bipinnately compound leaves.

The holotype, allotype, and paratypes are in my collection.

*Cryptulocephalus quercinus*, n. sp.

This is the first species in this genus known to me in which the frons of male and female are equally convex; the scape is also very short and bears a large tuft of hair in the female.

**Male.**—Length 1.0 mm. (paratypes: male 0.8-1.1, female 1.2-1.5 mm.), 2.4 times as long as wide; color very dark brown.

Frons convex, narrowly, transversely impressed just above epistoma; rugulose-reticulate, the punctures fine; vestiture moderately abundant, conspicuous, subplumose, moderately short. Scape only slightly longer than pedicel; bearing several long setae.

Pronotum 0.81 times as long as wide; widest near middle, subcircular in outline; anterior margin armed by three small teeth (four in paratypes); summit at middle; rather high, anterior slope rather coarsely asperate; posterior area smooth, shining, the punctures sparse, very minute; vestiture consisting of stout erect hair posteriorly, of bifid scales in asperate area.

Elytra 1.6 times as long as wide. 1.9 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, the punctures of moderate size and depth; interstriae almost smooth, as wide as striae, the punctures fine, uniseriate. Declivity rather steep, convex; essentially as on disc but surface more irregular. Vestiture consisting of fine, short, strial hair and rows of erect interstrial scales; each scale one and one-half times as long as strial hair, about two-thirds as long as distance between rows, similarly spaced within each row, each scale about twice as long as wide.

**Female.**—Similar to male except 2.8 times as long as wide; frons as in male; scape very slightly larger, bearing a large, long tuft of hair; anterior margin of pronotum unarmed; strial punctures not as deep, more widely spaced; declivity less clearly punctured; elytral scales more closely spaced within rows, very slightly longer, each scale about four times as long as wide.

**Type Locality.**—Thirty-seven km. west of Durango, Durango, Mexico.

**Type Material.**—The male holotype, female allotype, and 32 paratypes were collected at the type locality on June 4, 1965, about 2,000 m., No. 10, by S. L. Wood, from phloem tunnels in a small, shaded-out *Quercus* branch 2 cm. in diameter.

The holotype, allotype, and paratypes are in my collection.

*Cryptulocephalus arbuti*, n. sp.

This species is rather closely allied to *quercinus* Wood, described above, but it is distinguished by the larger, median, frontal impression, by the greatly reduced tuft of hair on the scape, by the rugulose-reticulate posterior areas on the pronotum, by the larger strial punctures, and by the longer, more slender interstrial scales.

**Male.**—Length 1.2 mm. (paratypes 1.0-1.3 mm., males average slightly smaller than females), 2.7 times as long as wide; color very dark brown.

Frons convex above, narrowly, rather strongly, transversely impressed just above epistoma, the impression extended slightly dorsal at center; vestiture confined to epistomal margin. Scape twice as long as pedicel, bearing about six setae; club oval very slightly longer than wide.

Pronotum 0.94 times as long as wide; essentially as in *quercinus* except posterior area minutely rugulose-reticulate, most of the punctures minutely granulate.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; outline about as in *quercinus*; striae not impressed, the punctures rather coarse, close, not sharply impressed; interstriae as wide as striae, minutely irregular, the punctures very fine, uniseriate. Declivity steep, convex; strial punctures slightly reduced in size, interstitial punctures minutely granulate. Vestiture consisting of very fine; moderately long strial hair and slightly longer, erect interstrial scales; each scale slender, equal in length to distance between rows, slightly closer within each row, each at least eight times as long as wide.

**Female.**—Similar to male except 3.0 times as long as wide; upper frons bearing rather abundant short, stout setae; scape bearing about a dozen setae; anterior margin of pronotum unarmed; elytral scales a little more slender.

**Type Locality.**—Thirteen km. west of Texmelucan, Puebla, Mexico.

**Type Material.**—The male holotype, female allotype, and 34 paratypes were collected at the type locality on June 13, 1967, 2,600 m., No. 27, by S. L. Wood, from twigs of *Arbutus* sp. The tunnels were immediately below the surface.

The holotype, allotype, and paratypes are in my collection.

*Cryptulocephalus caritus*, n. sp.

This species is allied to *arbuti* Wood, described above, but it is not closely related. It differs from *arbuti* by the less strongly convex frons which lacks a transverse impression, by the smaller, less abundant, pronotal asperities, and by the very different pronotal and elytral vestiture.

**Male.**—Length 1.2 mm. (paratypes 1.2-1.3 mm.), 2.7 times as long as wide; color dark brown.

Frons convex to epistomal margin, a moderately large fovea just below center; surface reticulate in marginal areas, smooth and shining on middle half, with a few scattered, small, punctures; vestiture inconspicuous. Scape elongate; club small, oval.
Pronotum 1.0 times as long as wide; widest near base, the sides very weakly arcuate, converging slightly to shallow constriction one-third pronotum length from the rather narrowly rounded anterior margin; anterior margin armed by four moderately large teeth; summit at middle, moderately high; anterior slope with fine asperities; posterior area minutely rugulate, the minute punctures obscure; vestiture slender, hairlike in both asperate and posterior areas.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; outline as in *querinus*; striae not impressed, the punctures fine; interstriae as wide as striae, with abundant, very minute points, the punctures very fine, obscure. Declivity steep, convex, as on disc except inter- strial punctures finely granulate. Vestiture consisting of very fine long, strial hair and erect interstrial setae; each interstrial seta on disc stout, hairlike, one and one-half times as long as strial hair, slightly longer than distance between rows, more closely spaced within each row; interstial setae becoming scalelike on declivity and very slightly longer, each scale at least six times as long as wide.

**Female.**—Similar to male except 2.9 times as long as wide; frons very weakly, transversely impressed just above epistomal margin; anterior margin of pronotum unarmed; interstitial granules on declivity very minute; interstial setae on declivity stout but essentially hairlike.

**Type Locality.**—Cerro Punta, Chiriqui, Panama.

**Type Material.**—The male holotype, female allotype, and 10 paratypes were collected January 11, 1961, 1,800 m., No. 411, by S. L. Wood, from broken branches of an unidentified tree.

The holotype, allotype, and paratypes are in my collection.

**Cryptulocleptus pumilus**, n. sp.

This species is rather closely allied to *subpilosis* Wood, but it may be distinguished in the male by the more slender body form, and by the much smaller strial punctures, and, in the female, by the more deeply concave frons and by the limitation of vestiture in the frontal concavity to a narrow band on upper margin.

**Male.**—**Length 0.8 mm.** (paratypes: male 0.8-0.9, female 1.0-1.1 mm.), 2.3 times as long as wide; color yellowish brown.

Frons convex, narrowly, transversely impressed just above epistomal margin, more strongly in median area; surface shining, rather coarsely reticulate; vestiture confined to epistomal margin. Antennal club rather narrowly ovate; devoid of sutures.

**Pronotum 0.90 times as long as wide; widest a third from base, sides evenly arcuate to the rather broadly rounded anterior margin; anterior margin armed by four small teeth; summit just behind middle, rather well developed; asperities on anterior slope coarse; posterior area shining, minutely rugulose-reticulate, the fine punctures obscure; vestiture largely scalelike.

**Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, the punctures very small but distinct; inter- strial somewhat irregular, shining, twice as wide as striae, the squamiformes punctures equal in size to those of striae but more widely spaced. Declivity rather steep, convex; sculpture as on disc but all punctures very slightly smaller. Vestiture consisting of minute, fine, strial hair and rows of erect, interstrial scales; each scale twice as long as strial hair, almost as long as distance between rows, about twice as long as wide, strongly tapered toward their bases.

**Female.**—Similar to male except 2.5 times as long as wide; frons rather deeply concave on median two-thirds to veil above eyes, with a row of stout, subplumose setae on upper margin; scape bearing a small tuft of long hair; anterior margin of pronotum unarmed; strial punctures equal in size but less distinct; elytral scales three times as long as wide.

**Type Locality.**—Fifty-three km. south of Colima, Colima, Mexico.

**Type Material.**—The male holotype, female allotype, and 56 paratypes were collected at the type locality on June 27, 1965, about 700 m., No. 122, by S. L. Wood, from an unidentified desert shrub.

The holotype, allotype, and paratypes are in my collection.

**Cryptulocleptus mendicus**, n. sp.

This species is closely allied to *pumilus* Wood, described above, but it may be distinguished by the smoother elytral surface, by the much more slender elytral scales, and, in the female, by the less strongly concave frons that is devoid of special setal ornamentation.

**Male.**—**Length 0.9 mm.** (paratypes: male 0.9-1.0, females 1.1-1.3 mm.), 2.4 times as long as wide; color yellowish brown, some specimens darker.

Frons as in *pumilus*; pronotum also as in *pumilus* except six teeth on anterior margin larger, the posterior area more finely reticulate.

**Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, narrowly rounded behind; striae not impressed, the fine punctures spaced by two diameters of a puncture; interstrial shining, marked by irregular lines, twice as wide as striae, the punctures distinctly smaller than those of striae. Declivity rather steep, convex, essentially as on disc except punctures much smaller. Vestiture consisting of very minute strial hair and rows of erect interstrial scales; each scale three times as long as strial hair, slightly shorter than distance between rows of scales, each about three times as long as wide.

**Female.**—Similar to male except 2.9 times as long as wide; frons concave on median two-thirds to upper level of eyes, not specially ornamented by setae; scape bearing a small tuft of long hair; anterior margin of pronotum unarmed; elytral punctures much more obscure; elytral scales more slender, each about six times as long as wide.

**Type Locality.**—Eleven km. south of Colima, Colima, Mexico.

**Type Material.**—The male holotype, female allotype, and 72 paratypes were collected at the type locality on June 28, 1965, about 1,000 m., No. 120, by S. L. Wood, from an unidentified thornless, leguminous, desert, shrubby tree. Additional paratypes were taken in Mexico as follows: 19 at 3 km. W. Armeria, Colima, June
The holotype, allotype, and paratypes are in my collection.

Cryptulocleptus acares, n. sp.

This species is rather closely related to mendicus Wood, described above, but it is distinguished by the larger size, by the more irregular, more deeply punctured elytra, and by the larger, more closely spaced interstitial scales.

**Male.**—Length 1.2 mm. (paratypes: males 1.1-1.2, females 1.3-1.4 mm.), 2.2 times as long as wide; color yellowish brown, the elytra darker.

Frons and pronotum as in mendicus, except posterior area of pronotum almost smooth and shining.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; outline about as in mendicus; striae not impressed, the punctures rather coarse; interstriae as wide as striae, the punctures rather large, uniseriate. Declivity steep, convex; sculpture about as on disc except interstitial punctures closer. Vestiture consisting of minute strial hair and rows of erect interstitial scales; each scale two-thirds as long as distance between rows, similarly spaced within rows; each scale twice as long as wide.

**Female.**—Similar to female of mendicus except 2.7 times as long as wide; frons somewhat more deeply impressed, with a few minute granules in upper third of impression; strial and interstriae punctures closer and more distinct, the general surface more irregular; declivity much more coarsely, deeply punctured; interstitial scales much closer, each four to six times as long as wide, very slightly longer.

**Type Locality.**—Thirty km. southeast of El Cameron, Oaxaca, Mexico.

**Type Material.**—The male holotype, female allotype, and 25 paratypes were collected at the type locality on June 21, 1967, near 1,000 m., No. 80, by S. L. Wood, from the branch of an unidentified tree (probably leguminose).

The holotype, allotype, and paratypes are in my collection.

Cryptulocleptus mirus, n. sp.

This species is rather closely related to acares Wood, described above, but it may be distinguished by the more deeply impressed female frons above, by the more coarsely sculptured posterior areas of the pronotum, and by the much finer declival punctures.

**Male.**—Length 1.0 mm. (paratypes: male 1.0-1.1, female 1.2-1.4 mm.), 2.2 times as long as wide; color yellowish brown.

Frons similar to acares but more strongly convex. Pronotum as in acares except reticulation in posterior areas tending to be very slightly more rugosulate.

Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; outline as in acares; striae not impressed, the punctures rather coarse, more sharply impressed than in acares; interstriae irregular but much smoother than in acares, as wide as striae, the punctures rather small and more widely spaced than in acares. Declivity steep, convex; surface smoother, the punctures very slightly smaller than on disc. Vestiture as in acares except interstitial scales very slightly more widely spaced.

**Female.**—Similar to female of acares except 2.8 times as long as wide; frons more abruptly impressed at upper limits of concavity; posterior areas of pronotum more strongly reticulate; elytral surface less rugosulate; declivital punctures reduced to very fine strial and interstitial punctures; elytral scales similar, but less abundant.

**Type Locality.**—Thirty-eight km. south of Matías Romero, Oaxaca, Mexico.

**Type Material.**—The male holotype, female allotype, and 40 paratypes were collected at the type locality on June 21, 1967, 250 m., No. 92, by S. L. Wood, from branches 1 to 5 cm. in diameter of a leguminose shrub having a yellow, mimosa-like flower.

The holotype, allotype, and paratypes are in my collection.
Cryptocleptus obesus, n. sp.

Apparantly this species is more closely allied to columbianus Blackman than to other known species, but it is distinguished by the stouter body, shorter antennal scape: and by the less closely placed interstrial scales.

Male.—Length 1.0 mm. (paratypes: male 1.04-2, female 1.2-1.4 mm.), 2.0 times as long as wide; color reddish brown, the elytra black (lighter in less mature specimens).

Frorns plane convex almost to upper level of eyes; minutely punctate above, becoming smoother below; vestiture consisting of a few short subpubescent setae over flattened area. Scape short, little longer than pedicel, bearing a small tuft of hair; club moderately large, oval.

Pronotum 0.86 times as long as wide; widest one-third from base, sides rather strongly arcuate converging toward the narrowly rounded anterior margin; anterior margin armed by four teeth, the median pair larger; summit behind middle, well developed; anterior area coarsely asperate; posterior area very minutely rugulose, the punctures obscure; vestiture largels scalelike.

Elytra 1.15 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on slightly more than half basal, rather broadly rounded behind; striae not impressed, the punctures small, obscure, interstriae wider than striae, the punctures fine, umbilicate. Declivity steep, broadly convex; surface minutely rugulose, as on disc except interstrial punctures closer. Vestiture consisting of interstrial rows of erect scales, each scale less than twice as long as wide.

Female.—Similar to male except 2.3 times as long as wide; frorns shallowly concave to upper level of eyes; scape larger, broadly triangular, bearing a large tuft of long hair; anterior margin of pronotum unarmed; elytra minutely rugulose, all punctures obscure.

Type Locality.—Thirty km. southeast of El Cameron, Oaxaca, Mexico.

Type Material.—The male holotype, female allotype, and three paratypes were collected at the type locality on June 21, 1967, near 1,000 m., No. 78, by S. L. Wood, from the twigs of the same tree that harbored the preceeding species, obesus.

Pronotum 0.89 times as long as wide; widest two-fifths from base, the sides and anterior margin equally rounded on an almost circular arc; anterior margin armed by two small teeth; summit at middle, broad; anterior slope very coarsely asperate; posterior areas almost smooth, obscurely reticulate, shining; small scales almost obsolete except at margins.

Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; widest at base, the sides straight on basal two-thirds, very feebly converging posteriorly, broadly rounded behind; striae not impressed, the punctures small, shallow, somewhat obscure; interstriae wider than striae, minutely subrugulose, shining, the punctures fine, obscure. Declivity steep, convex; striae punctures greatly reduced, becoming obsolete; interstriae punctate-fine granulate. Vestiture consisting of minute, fine, subpubescent hair and rows of erect interstrial scales; each scale on disc slender, elongate, slightly longer than distance between rows, becoming shorter but not narrower toward declivity, on declivity each scale equal in length to little more than half distance between rows, about twice as long as wide. Posterior margin of sternum 5 narrowly rounded, projecting slightly.

Female.—Similar to male except 2.3 times as long as wide; frontal excavation slightly deeper with median area near epistoma slightly elevated; mandibular ridge absent; scape wider, bearing a small tuft of hair; margin of pronotum unarmned; discal scales on elytra slightly shorter; sternum 5 less strongly produced.

Type Locality.—Thirty km. southeast of El Cameron, Oaxaca, Mexico.

Type Material.—The male holotype, female allotype, and three paratypes were collected at the type locality on June 21, 1967, near 1,000 m., No. 78, by S. L. Wood, from the twigs of the same tree that harbored the preceeding species, obesus.

The holotype, allotype, and paratypes are in my collection.

Cryptocleptus spicatus, n. sp.

This species and the next one form a new species group within the genus. They differ from all representatives of the genus in having the last visible male abdominal tergum very narrow, produced mediad into a projecting mucro; in the female a similar projecting mucro is formed by the last visible sternum; the female frons is also concave.

Male.—Length 1.7 mm. (paratypes 1.5-1.8 mm.), 2.4 times as long as wide; color dark brown, summit of pronotum reddish brown.

Frorns convex above, becoming more nearly flattened on lower third; surface rugulose-reticulate and obscurely punctured: an indefinite, median, subovate impression just below upper level of eyes; vestiture fine, short, inconspicuous except long and conspicuous along epistomal margin. Scape elongate.

Pronotum 0.90 times as long as wide; widest a third from base, sides arcuate, a weak constriction on anterior third, rather broadly rounded in front; anterior margin armed by about eight small teeth; summit just behind middle, moderately high; asperities on anterior slope rather large; posterior area rugulose-reticulate, a few fine granules behind summit; vestiture hairlike.
Elvtra 1.5 times as long as wide. 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, the punctures very small, obscure; interstriae almost twice as wide as striae, very finely rugulose, the punctures very fine, their anterior margins very finely granulate. Declivity convex, steep; sculpture essentially as on disc. Vestiture consisting of fine, moderately long, strial hair and rows of slightly longer interstrial bristles; each bristle about two-thirds as long as distance separating rows, separated within rows by distances equal to length of bristle, bristles becoming scalelike on declivity, each scale there at least three times as long as wide. Last visible tergum narrowly produced into a micro-like process that projects beyond elytral apex.

Female.—Similar to male except 2.6 times as long as wide; frons shallowly concave to vertex, low, median half smooth, shining and ascending toward epistomal margin; anterior margin of pronotum unarmed; interstrial setae on disc fine, hairlike, bristlelike on declivity; mucro formed by last visible sternum; last tergum rounded on posterior margin.

Type Locality.—Cerro Punta, Chiriqui, Panama.

Type Material.—The male holotype, female allotype, and 48 paratypes were collected at the type locality on January 11, 1964. 1,800 m. No. 382, from cambium tunnels in an unidentified log about 1 m. in diameter.

The holotype, allotype, and paratypes are in my collection.

Cryptuloceleptus subulatus, n. sp.

This species is rather closely related to spicatus Wood, described above, but it may be distinguished by the much larger and deeper strial punctures, by the longer, broader, elytral scales, and by the much more strongly impressed female frons.

Male.—Length 1.4 mm. (paratypes 1.3-1.7 mm.), 2.3 times as long as wide; color very dark brown to black, pronotal summit reddish brown.

Frons and pronotum as in spicatus except part of pronotal vestiture stout.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; outline as in spicatus; striae not impressed, the punctures rather large, deep, sharply impressed; interstriae almost smooth, shining, one and one-half times as wide as striae, the uniseriate punctures finely granulate. Declivity steep, convex; striae very finely impressed, the punctures more obscure. Vestiture consisting of short, fine strial hair (some flattened on declivity), and rows of longer, interstrial scales; each scale slightly more than half as long as distance between rows, separated within rows by distances equal to length of scale, each about twice as long as wide. Tergal mucro about as in spicatus.

Female.—Similar to male except 2.6 times as long as wide; frons rather deeply concave on median three-fourths from epistoma to vertex, a small, smooth, median area on lower half, most females ornamented by a small, sparse tuft of hair at upper margin of concavity; anterior margin of pronotum unarmed; striae punctures not as deep, perhaps smaller; interstrial scales very slightly longer and more slender, each scale about four times as long as wide; tergal mucro replaced by sternal mucro as in spicatus.

Type Locality.—Volcan Pacaya, Esquintla, Guatemala.

Type Material.—The male holotype, female allotype, and 57 paratypes were collected at the type locality on June 1, 1961, 1,300 m., No. 700, by S. L. Wood, in tunnels in the phloem of branches less than 8 cm. in diameter of a tree named Caldo de Frijol by a local woodcutter. The local host name obviously was derived from the odor of freshly cut wood.

The holotype, allotype, and paratypes are in my collection.

Cryptuloceleptus mucronatus, n. sp.

While most of the generic characters of Cryptuloceleptus clearly fit this species, it is unique in having the elytral apices acuminate extended to form a short mucro as seen in Micracis or possibly Micracisella. The mucro appears to be a secondary acquisition that should not have a bearing on the generic placement of this species.

Male.—Length 1.3 mm. (paratypes 1.2-1.4 mm.), 2.5 times as long as wide; color dark reddish brown.

Frons convex, with a feebly impression just above epistoma; surface rather coarsely rugulose above, more finely below, with a small, median, smooth area on lower third; vestiture short, sparse. Scrope elongate, with fewer than a dozen setae; club broadly oval, unmarked by any indication of sutures.

Pronotum 1.0 times as long as wide; widest two-fifths from base, the sides weakly arcuate, moderately constricted a fourth of pronotum length behind the broadly rounded anterior margin; anterior margin armed by four minuscule teeth; summit at middle, moderately high; anterior slope armed by many small asperities; posterior areas rather coarsely reticulate, with moderately abundant, fine, isolated granules behind summit; vestiture of stout, hairlike setae.

Elytra 1.5 times as long as wide. 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind except for the very short, sutural mucro; striae not impressed, the punctures fine, distinct; interstriae minutely subrugulose, wider than striae, the punctures small, obscure, becoming granulate toward declivity. Declivity convex, very steep; strial punctures larger than on disc but very obscure; interstrial punctures replaced by rather large rounded granules. Vestiture consisting of very fine, moderately long strial hair and rows of erect interstrial scales; the scales slightly shorter and more slender on disc; each scale on declivity spaced within and between rows by distance equal to length of scale, each about four times as long as wide. Apex with a very short mucro.

Female.—Similar to male except 2.6 times as long as wide; frons less strongly convex, less coarsely rugulose, with median fovea near center; anterior margin of pronotum unarmed; elytral scales more slender, at least six times as long as wide on declivity.

Type Locality.—La Lima, Cortez, Honduras.

Type Material.—The male holotype, female allotype, and 14 paratypes were collected on May 5, 1964, 70 m., No. 572, by S. L. Wood, from tunnels in the xylem of stems 1 cm. in diameter from an unidentified shrubby, woody vine.
The holotype, allotype, and paratypes are in my collection.

_Thysanoes neotropicalis_, n. sp.

This species is more closely related to _mexicanus_ Wood than to others in the genus, but it is larger, more slender, more finely striate, and it has the female front more strongly impressed. The is the first species of _Thysanoes_ reported south of Mexico.

**Female.**—Length 2.1 mm. (paratypes: females 2.0–2.2, males 1.5–1.9 mm). 3.2 times as long as wide; color medium brown, pronotum lighter on type (only).

Frons broadly, somewhat transversely impressed from epistoma to upper level of eyes, the central area more narrowly impressed, subovate; epistomial area smooth and shining to subovate impression, sides and above finely, obscurely punctured and finely, closely, subacutely granulate; vestiture inconstant. Tuft of setae on scape much taller than in _mexicanus_.

Pronotum 1.2 times as long as wide; slightly wider near middle, the sides straight and diverging on basal half, converging slightly anteriorly toward the broadly rounded subcircular anterior margin; summit almost one-third from anterior margin; posterior area reticulate and very finely punctured; vestiture confined to marginal areas consisting of flattened bristles.

Elytra 2.1 times as long as wide 1.8 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, the punctures small, shallow; interstriae about twice as wide as striae, subshining, irregular but not clearly marked by lines or punctures. Declivity convex, steep; surface dull, strial punctures smaller than on disc, perhaps deeper; interstriae with occasional fine granules. Vestiture confined to declivity, consisting of erect interstrial scales with an additional, partial row at suture; each scale three to four times as long as wide.

**Male.**—Similar to female except smaller. 1.8 mm., stouter, 26 times as long as wide; frons less extensively impressed; anterior margin of pronotum armed by ten serrations; elytra with strial punctures much larger and deeper, the interstrial punctures uniseriately granulate toward declivity, both strial punctures and moderately large interstrial granules continuing to apex of declivity; declival vestiture longer and extending well onto disc.

**Type Locality.**—San Ignacio de Acosta, San José Prov., Costa Rica.

**Host.**—_Calliandra confusa_.

**Type Material.**—The female holotype, male allotype, and eight paratypes were collected at the type locality on June 11, 1967, 2,100 m., by S. L. Wood, from _Quercus_ branches.

The holotype, allotype, and paratypes are in my collection.

_Thysanoes subsulcatus_, n. sp.

This species is allied to _fimbribicornis_ LeConte, but it is distinguished by the less deeply impressed, more strongly reticulate female frons, by the more coarsely sculptured elytral disc, by the almost obsolete declival striae, and by the much broader scales on the elytral declivity.

**Female.**—Length 1.2 mm. (paratypes 1.8–2.2 mm). 3.0 times as long as wide; color yellowish brown.

Frons rather strongly, transversely impressed from epistomal margin to well above eyes, a small median impression just below center; entire surface rather strongly rugulose-reticulate; vestiture fine, short, sparse. Scape bearing a rather dense fringe of long hair.

Pronotum 1.08 times as long as wide; sides almost straight and parallel on basal half, distinctly constricted on anterior half, broadly rounded in front; anterior...
margin unarmed; summit in front of middle; posterior area reticulate, the punctures moderately abundant, rather small, shallow; vestiture of fine hair and stout bristles, rather short.

_Elytra_ 1.8 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, broadly rounded behind; striae not impressed, the punctures small, distinct; interspaces twice as wide as striae, irregularly subrugose, the punctures small, obscure. Declivity convex, steep, confined to posterior fourth; striae very weakly impressed, the punctures minute, distinct; interspaces almost smooth, with very fine, uniseriate, squamulose granules, those on 3 very slightly larger. Vestiture of minute striae hair and uniseriate rows of erect interstriae scales; each scale on disc half as long as distance between rows, three times as long as wide; declivital scales three-fourths as long as distance between rows, two to three times as long as wide; a partial supplemental row along suture.

_Male._—Similar to female except frontals impressed, not reaching upper level of eye, the central impression more pronounced, sculpture of upper half granulate; anterior margin of pronotum armed by six teeth; declivital granules very slightly larger.

_Type Locality._—Twenty-four km. south of Mazamitla, Jalisco, Mexico.

_Type Material._—The female holotype, male allotype, and eight paratypes were collected at the type locality on June 22, 1965, 2,500 m., by S. L. Wood, from branches of a leguminous tree.

The holotype, allotype, and paratypes are in my collection.

_Thysanos adonis, n. sp._

This species is allied to _mexicanus_ Wood, but it is distinguished by the larger size, by the subovate frons, by the absence of interstrial granules on basal half of disc, and by longer and much more slender interstrial declivital scales.

_Female._—Length 2.9 mm. (paratypes 1.4-1.9 mm.), 2.6 times as long as wide; color dark brown, summit of pronotum reddish brown.

Frons convex above, transversely impressed on lower half of area below upper level of eye, a small median, subovate impression at center, ascending toward epistomal margin; surface densely, minutely, evidently subrugulus, punctated in convex area, becoming almost smooth toward epistoma; vestiture of sparse, moderately long, very stout bristles uniformly distributed on convex area. Scap bearing about a dozen long hairs.

_Pronotum_ 1.04 times as long as wide; sides almost straight and parallel on basal half, moderately constricted on anterior half, rather broadly rounded in front; anterior margin subcircular; summit at middle; rather broad; asperities on anterior slope rather coarse; posterior areas reticulate, the punctures minute, sparse, a few behind summit minutely granulate; vestiture of stout bristles.

_Elytra_ 1.6 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind; striae not impressed, the punctures small, distinct; interspaces about three times as wide as striae, the surface irregular, subrugulus, the punctures small, uniseriate, finely granulate on posterior half. Declivity convex, steep, restricted to posterior fourth; striae punctures obsolete, except some of them very finely granulate; interspace uniseriate, finely granulate; general surface somewhat dull. Vestiture of very minute striae hair and uniseriate rows of much longer, interstrial scales; each scale on disc about two-thirds as long as distance between rows, about four times as longer as wide; scales on declivity slightly longer than distance between rows, about six times as long as wide, with a smaller supplemental row at suture.

_Male._—Similar to female except anterior margin of pronotum more distinctly serrate; elytral granules smaller, the declivital striae punctures minute but visible; declivital scales broader, about four to five times as long as wide.

_Type Locality._—Twenty-nine km. west of Quiroga, Michoacan, Mexico.

_Type Material._—The female holotype, male allotype, and seven damaged paratypes were collected at the type locality on June 17, 1965, 2,200 m., by S. L. Wood, from _Quercus_ branches.

The holotype, allotype, and paratypes are in my collection.

_Micracisella monadis, n. sp._

This species is perhaps more closely allied to _hondurensis_ Wood than to other known species, but it is easily distinguished by the very different frontals sculpture, by the rows of rounded interstrial granules on the declivity, and by the distinctly elevated declivital interstriae 9.

_Female._—Length 1.7 mm. (paratypes 1.5-1.7 mm.), 2.9 times as long as wide; color dark brown.

Frons planoconvex from epistoma to well above eyes, the epistomal margin slightly elevated toward center; surface very minutely, longitudinally etched, approaching reticulation laterally; glabrous. Scape more than three times as long as pedicel, broad, bearing a large tuft of hair.

_Pronotum_ 1.1 times as long as wide; widest at middle, sides weakly arcuate on posterior two-thirds, weakly constricted on anterior third before the rather narrowly rounded anterior margin; anterior margin armed by two basally contiguous, small teeth; summit at middle broad; posterior areas coarsely reticulate with a few minute granules near and behind summit; a few scales on marginal areas.

_Elytra_ 1.7 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds, narrowly rounded behind; striae not impressed, the punctures very small, distinct; interstriae marked by lines, shining, three times as wide as striae, the punctures fine, obscure. Declivity convex, rather steep; striae punctures larger, deeper, very obscure; interstrial punctures replaced by small rounded granules. Apex of elytra subacuminate. Vestiture consisting of very short, fine, striae hair and rows of longer, erect, interstrial scales; each scale slightly shorter than distance between rows, similarly spaced within rows, each scale about four times as long as wide, gradually, strongly narrowed toward their bases.

_Male._—Similar to female except frons convex, a narrow, transverse impression just above epistoma, the surface finely rugose-reticulate, a few short, stout setae in lateral areas; tuft of hair on scape smaller; scape more slender; teeth on anterior margin of pronotum larger; declivital scales very slightly wider.

_Type Locality._—Volcan Colima, Jalisco, Mexico.

_Host._—_Struthanthus venetus._
Type Material.—The holotype, allotype, and seven paratypes were collected at the type locality on June 23, 1965, 2,500 m., No. 105, by S. L. Wood, from axial pith tunnels in twigs of the above named mistletoe.

The holotype, allotype, and paratypes are in my collection.

**Micracisella scitula**, n. sp.

This species is allied to *monadis* Wood, described above, but it is readily distinguished by the strongly convex frons, by the smaller, less numerous declivital interstitial granules, by the wider declivital scales, and by the presence of four teeth on the anterior margin of the pronotum.

**Male**.—Length 1.6 mm., 3.0 times as long as wide; color reddish brown.

Frons rather strongly convex, with a narrow, transverse impression just above epistomal margin; surface rather coarsely reticulate except almost smooth on small median area on lower half, a few very small granules scattered on upper half; vestiture sparse, very short in convex area, longer below.

Pronotum 1.2 times as long as wide; widest near middle, the sides very feebly arcuate, almost parallel on more than basal half, rather narrowly rounded in front; anterior margin armed by four small teeth, median pair slightly larger; summit broad, near middle; posterior area coarsely reticulate, a few shining points evidently represent obsolete punctures; vestiture reduced to a few very stout bristles in marginal areas.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on slightly more than basal two-thirds, rather broadly rounded behind except subacuminate at suture; striae not impressed, the punctures small, distinct, anterior margins of some of them very feebly elevated; interstitial shining, subrugulose, the punctures two-thirds as large as those of striae, shallow, some obscure. Declivity convex, rather steep; striae punctures somewhat obscure; interstitial punctures on upper half replaced by rounded granules; subreticulate toward suture near apex. Vestiture largely abraded on disc of type, evidently shorter than on declivity; on declivity consisting of rows of erect, interstitial scales, each scale almost as long as distance between rows, more widely spaced within each row except on 1, each scale broad, averaging about twice as long as wide. Apex acuminate, the micro short; but not all divericate.

**Type Locality.**—Fourteen km. east of Huatusco, Veracruz, Mexico.

**Type Material.**—The male holotype was collected at the type locality on July 7, 1967, near 1,300 m., No. 173, by S. L. Wood, from *Quercus* twigs.

The holotype is in my collection.

**Micracisella mitidula**, n. sp.

This species is allied to *monadis* Wood, described above, but it may be distinguished by the reticulate-granulate frons, by the slender declivital interstitial scales, by the much smaller declivital interstitial granules, and by the presence of four marginal teeth on the pronotum.

**Female**.—Length 1.9 mm., 3.1 times as long as wide; color black.

Frons convex, less strongly on lower half, epistomal margin weakly elevated; surface very finely reticulate-granulate, reduced to minute points on small median area near epistoma; vestiture consisting of rather sparse, conspicuous, subplumose setae of moderate length to vertex. Scape twice as long as pedicel, bearing a small tuft of long hair.

Pronotum 1.1 times as long as wide; widest just behind middle, sides rather strongly arcuate, weakly constricted on anterior third, rather narrowly rounded in front; anterior margin armed by six small teeth of equal size; summit near middle, rather broad; posterior area minutely reticulate-granulate, with a few minute, almost flat, granules toward summit; vestiture rather stout, moderately abundant, rather long.

Elytra 2.0 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on basal three-fourths, narrowly acuminate behind; striae not impressed, the punctures small, shallow; interstitial twice as wide as striae, somewhat irregular, the punctures very fine, uniserate. Declivity convex, rather steep; striae punctures slightly deeper than on disc; interstitial punctures replaced by fine granules; apex subacuminate, micro not developed, not at all divericate. Vestiture consisting of very fine, moderately long strial hair and rows of erect interstitial scales, slightly longer on declivity; each scale on declivity slightly longer than distance between rows, similarly spaced within each row, each about six times as long as wide.

**Type Locality.**—Ten km. northeast of Tezuitlan, Puebla, Mexico.

**Type Material.**—The female holotype was collected at the type locality on July 2, 1967, 1,600 m., No. 142, by S. L. Wood, from an axial pith tunnel in *Rubus* sp. A second female specimen, almost certainly this species but not designated as a paratype, was taken 26 km. east of Morelia, Michoacan, Mexico, June 14, 1965, 2,500 m., S. L. Wood, from an *Arbutus* sp. twig.

The holotype is in my collection.

**Micracisella nigrella**, n. sp.

This species is allied to *nigra* Wood, but it is distinguished by the coarser sculpture of strial punctures and declivital granules, by the larger, coarser, more abundant interstitial scales, and by the different arrangement of marginal teeth on the pronotum.

**Female**.—Length 1.7 mm. (paratypes 1.5-1.8 mm.), 3.0 times as long as wide; color almost black, summit of pronotum reddish brown.

Frons convex on upper half, transversely impressed on lower half, an indistinct median impression toward center; vestiture sparse, of very short, fine, subplumose setae. Scape twice as long as pedicel, bearing a moderately large tuft of long hair.

Pronotum 1.14 times as long as wide; widest just behind middle, the sides weakly arcuate on more than basal half, rather narrowly rounded in front anterior margin armed by two rather large teeth; summit at middle, rather broad; posterior area minutely reticulate-
granulate, with moderately abundant, isolated, very fine granules; vestiture of rather short, broad scales.

Elytra 1.9 times as long as wide, 1.7 times as long as pronotum; outline as in nitidula; striae not impressed, the punctures fine, distinct, shallow, interstriae with fine lines, twice as wide as striae, the punctures very fine, half as large as those of striae. Declivity convex, rather steep; interstrial punctures about as large as those of striae; apex acuminate, the sutural apex distinctly, shallowly emarginate. Vestiture consisting of rows of erect interstrial scales; each scale very slightly shorter than distance between rows, similarly spaced within rows, each about two and one-half to three times as long as wide; a supplemental sutural row of smaller scales on declivity.

Male.—Similar to female except frons slightly more convex; scape without tuft of hair; elytral scales very slightly larger.

Type Locality.—Volcan de Agua, Esquinilla, Guatemala.

Type Material.—The female holotype, male allotype, and 81 paratypes were collected at the type locality on May 19, 1964, 1,000 m., No. 603, by S. L. Wood, from branches of an unidentified shrub somewhat resembling Rhus.

The holotype, allotype, and paratypes are in my collection.

Micracisella similis, n. sp.

This species is allied to nigra Wood, but it is distinguished by the more slender body form, by the less strongly convex frons, with a slight median impression above epistoma, and much greater development of the vestiture, and by the more strongly reticulate pronotal disc.

Female.—Length 1.5 mm. (paratypes 1.4–1.5 mm.), 3.0 times as long as wide; color black, summit of pronotum reddish brown.

Frons planoconvex, flattened toward center, gradually ascending to epistomal margin on lower fourth; surface minutely reticulate-granulate, smoother medially toward epistoma; vestiture moderately long and abundant toward lateral areas, subplumose. Scape twice as long as pedicel, bearing a small tuft of long hair.

Pronotum 1.16 times as long as wide; widest at middle, sides on basal half straight, almost parallel, rather narrowly rounded in front; anterior margin armed by two moderately large, basally contiguous teeth; summit at middle, broad; posterior areas minutely reticulate-granulate, with a few, fine scattered granules; vestiture short, scalelike.

Elytra 1.9 times as long as wide, 1.7 times as long as pronotum; outline as in nitidula; striae not impressed, the punctures small, shallow; interstriae marked by lines, shining, slightly less than twice as wide as striae, the uniseriate punctures very fine. Declivity convex, rather steep; strial punctures somewhat reduced; interstrial punctures replaced by fine granules on upper half, almost obsolete below; general surface granulose toward sutural apex; apex acuminate, the sutural apex shallowly emarginate. Vestiture consisting of minute, fine, strial hair and uniseriate rows of longer, erect, interstrial scales; each scale slightly shorter than distance between rows, similarly spaced within each row, each scale on declivity about three times as long as wide.

Male.—Similar to female except frons more nearly convex, the frontal vestiture somewhat shorter; reduction of interstrial tubercles on lower half of declivity less pronounced.

Type Locality.—Volcan Ceboruco, Nayarit, Mexico.

Type Material.—The female holotype, male allotype, and seven paratypes were collected at the type locality on July 5, 1965, 1,200 m., No. 189, by S. L. Wood, from axial pit tunnels in Serjania sp.

The holotype, allotype, and paratypes are in my collection.

M. vesicula, n. sp. This species is allied to similis Wood, described above, but it may be distinguished by the coarser strial punctures, by the absence of interstrial granules on the declivity, and by the large, broader, interstrial scales.

Female.—Length 1.4 mm. (allotype 1.35 mm.), 3.0 times as long as wide; color dark brown, summit of pronotum reddish brown.

Frons as in similis but less strongly flattened. Scape twice as long as pedicel, bearing a tuft of long hair.

Pronotum 1.17 times as long as wide; outline as in similis; anterior margin armed by two moderately large, subcontiguous teeth; posterior area minutely reticulate-granulate, with obscure, subgranulate punctures; vestiture of rather abundant, short scales, each twice as long as wide.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; outline as in nitidula; striae not impressed, the punctures rather fine, not always clearly defined; interstriae irregular, almost subrugulose, as wide as striae, the uniiseriate punctures fine. Declivity convex, rather steep; strial punctures deeper than on disc, the interstrial punctures equal in size to those of striae; apex acuminate, shallowly emarginate at sutural apex. Vestiture consisting of very fine, short, strial hair and interstrial rows of erect, uniseriate scales, each scale about as long as distance between rows, similarly spaced within each row, each about three times as long as wide; a supplemental row of smaller, sutural scales on declivity.

Male.—Similar to female except frons more strongly convex, the frontal vestiture shorter; tuft of hair on scape much smaller; teeth on anterior margin of pronotum slightly larger.

Type Locality.—Two km. north of Cerro Gordo, Veracruz, Mexico.

Type Material.—The female holotype and male allotype were collected at the type locality on July 6, 1967, 1,000 m., No. 166, by S. L. Wood, in axial pit tunnels in Serjania sp.

The holotype and allotype are in my collection.

M. squamata, n. sp. This species is allied to nigra Wood and the three preceding species, but it is easily distinguished from these and all other representatives of the genus by the much more widely spaced teeth on the anterior margin of the pronotum, by the scalelike, small, strial setae in addition to
those of the interstriae, and by the more strongly divaricate elytra at the sutural apex.

**Female.**—Length 1.4 mm. (paratypes 1.3-1.5 mm.). 3.0 times as long as wide; color black, summit of pronotum reddish brown, vestiture white.

Frons convex above, becoming flattened below, then ascending slightly to epistomial margin; surface reticulate-granulate above, becoming almost smooth in central area below except for a few fine points; vestiture rather abundant and long in large dorsolateral areas. Scape about twice as long and slightly wider than pedicle, bearing a small tuft of long hair.

Pronotum 1.1 times as long as wide; widest on basal half; sides almost straight and parallel, then acutely rounded to constriction on anterior third, narrowly rounded in front; anterior margin armed by two, rather large, basally contiguous teeth; summit rather indefinite, at middle; small asperities continue to just behind summit, isolated granules continue to base; surface of posterior area coarsely reticulate; vestiture of small, short scales.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds, then narrowly rounded to blunt apex; striae not impressed, the punctures very small; interstriae shining, marked by lines, twice as wide as striae, the uniseriate punctures fine, somewhat obscure. Declivity convex, rather steep; stria punctures largely obsolete; interstria punctures replaced by rounded granules; apex divaricate, the emargination as wide as width of antennal club and half as deep. Vestiture consisting of very minute, very fine strial hair and rows of longer, suberect, interstrial scales, each scale slightly shorter than distance between rows, similarly spaced within rows except closer on 1, each scale about four times as long as wide.

**Male.**—Similar to female except frons more strongly convex, the setae more evenly distributed; elytral scales slightly wider, about three times as long as wide.

**Type Locality.**—Two km. north of Cerro Gordo, Veracruz Mexico.

**Type Material.**—The female holotype, male allotype, and one female paratype were collected at the type locality on July 6, 1967, 1,000 m. No. 166, by S. L. Wood, from axial pith tunnels in *Seryania* sp.

The holotype, allotype, and paratype are in my collection.

**Micracis costaricensis**, n. sp.

The only species known to me that is at all similar to this one is *carinulatus* Wood. This species may readily be distinguished from *carinulatus* by the dull surfaces, by the more irregularly punctured elytra, by the more delicate, more strongly flattened interstrial scales, and by the slightly impressed second declivital interspace.

**Female.**—Length 2.7 mm. (paratypes 2.2-2.8 mm.). 3.2 times as long as wide; color rather dark reddish brown.

Frons strongly, transversely impressed and slightly concave from epistoma to well above eyes, upper half of impressed area with a fine, low median carina; surface coarsely reticulate except smooth just above epistoma; vestiture consisting of sparse, short setae in reticulate area, with a fringe of long subplumose hair along margin of impressed area above level of eyes. Scape flattened, triangular, ornamented by a fringe of long hair; sutures of club strongly procurred, 1 reaching middle, 2 extending three-fourths of club length from its base.

Pronotum 1.3 times as long as wide; widest on basal half, sides almost straight and parallel on slightly more than basal half, rather broadly rounded in front; anterior margin armed by 12 rather coarse, isolated teeth; summit in front of middle; rather coarsely reticulate behind summit with rather sparse, fine, subgranulate punctures. Vestiture consisting of rather short, stout, delicate, white setae.

Elytra 1.9 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind to the
short, projecting sutureal apex; striae not impressed, the punctures small, shallow, distinct; interstriae about three times as wide as striae, irregular, punctures and other features obscured by irregular surface features. Declivity evenly convex, very steep; striae slightly impressed, the punctures deeper than on disc; interstriae weakly convex, with lower half of 2 somewhat impressed; all interspaces bearing median rows of fine, rounded granules, those in lateral areas a little larger; terminal macro as in other species of this genus. Vestiture consisting of rows of fine stria, hair and delicate, very slender interstitial scales of equal length; each scale almost equal in length to distance between rows of scales; easily abraded.

Male.—Similar to female except slightly smaller, 2.4 mm., stouter, 2.8 times as long as wide; frons convex with a slight transverse impression just above epistoma, surface finely granulate, the vestiture greatly reduced; scape not dilated, tuft of hair almost obsolete; pronotum and elytra very slightly more coarsely sculptured.

Type Locality.—Volcan Poas, Heredia Prov., Costa Rica.

Host.—Calliandra confusa (paratypes).

Type Material.—The holotype, allotype, and 41 paratypes were collected at the type locality on June 19, 1966, at an elevation of about 2,000 m., by S. L. Wood, from branches of a leguminose shrub. Additional paratypes were taken in Costa Rica as follows: 18 from Tapanti, Cartago Prov., 1,400 m., Aug. 17, 1963; 25 from Santa Ana, San José Prov., 1,400 m., Oct. 4, 1963; and 3 from San Ignacio de Acosta, San José Prov., 1,500 m., July 5, 1963, all taken by S. L. Wood, from Calliandra confusa. Eleven specimens not included in the type series are from San Ignacio de Morazan, Honduras, April 18, 1964, 700 m., from Salix guatemalensis.

The holotype, allotype, and paratypes are in my collection.

Mircacis carinulus, n. sp.

Similar to costaricensis Wood, described above, but smaller, the declival striae not impressed, the impression of the female frons not reaching upper level of eyes with the median carina rather sharply elevated.

Female.—Length 2.1 mm. (paratypes 1.6-2.1 mm.); 3.1 times as long as wide; color yellowish brown.

Frons broadly concave from epistoma to upper level of eyes, upper half divided by a fine, low carina, surface smooth and shining just above epistoma, then finely punctured and becoming coarsely reticulate on upper half; vestiture consisting of short, stout, close setae in concave area, and long, curved, subplumose hairs along upper margin of cleviturn. Antenna as in costaricensis, except wider.

Pronoturn as in costaricensis except anterior margin unarmel.

Elytra as in costaricensis except surface of disc a little more irregular and strial punctures less distinct. Declivity evenly convex except for terminal macro; strial punctures very slightly impressed; interstriae with small, rather obscure granules. Vestiture consisting of moderately long, rather abundant coarse strial and interstrial setae; those on median row of each interspace slightly longer.

Male.—Similar to female except frons convex and finely granulate with a slight transverse impression above epistoma; scape less strongly dilated; anterior margin of pronotum armed by about eight small serrations; and median rows of elytral setae more nearly scalelike.

Type Locality.—Playón, Puntarenas Prov., Costa Rica.

Host.—Rheedia edulis.

Type Material.—The female holotype, male allotype, and 20 paratypes were collected at the type locality on February 22, 1964, at an elevation of about 50 m., by S. L. Wood, from branches of the above host. Two additional paratypes were taken at Fort Clayton, Canal Zone, Panama, on December 22, 1963 at about 30 m., by S. L. Wood, from a fallen limb of an unidentifelled tree.

The holotype, allotype, and paratypes are in my collection.

Mircacis tribulatus, n. sp.

This species is very cosely related to costaricensis Wood, described above but it may be distinguished by the darker color, by the more slender form, by the armed anterior margin of the female pronotum, by the granulate, discal, interstitial punctures, and by the coarser declival granules.

Female.—Length 2.8 mm. (paratypes 2.2-2.8 mm.); 3.6 times as long as wide; color very dark brown.

Frons and antenna as in costaricensis.

Pronotum 1.2 times as long as wide; sides straight and parallel on basal two-thirds, rather broadly rounded in front; anterior margin armed by six small teeth; summit distinct, in front of middle; posterior areas reticulate-granulate, with sparse, moderately large, isolated granules to base; vestiture of fine hair and slender scales.

Elytra 2.3 times as long as wide, 2.9 times as long as pronotum; sides straight and parallel on basal three-fourths, narrowly mucronate behind; strial punctures very small, distinct; interstriae at least three times as wide as striae, subshining, marked by lines, the punctures fine, subgranulate; declivity steep, convex, confined to posterior fourth; interstitial punctures replaced by moderately large, rounded granules; apex mucronate. Vestiture consisting of fine striae and rows of longer, erect, interstitial scales, slightly longer on declivity; each scale on disc about six to eight times as long as wide, much more slender on declivity.

Male.—Similar to female except 2.9 times as long as wide; frons convex above, transversely impressed below, with a small median impression; scape smaller, narrower; teeth on anterior margin of pronotum larger; declival scales slightly longer.

Type Locality.—Twenty-six km. west of Texmelucan, Puebla, Mexico.

Type Material.—The female holotype, male allotype, and 9 paratypes were collected at the type locality on June 6, 1967, 2,900 m., No. 29, by S. L. Wood, from Salix.

The holotype, allotype, and paratypes are in my collection.
Micracis lepidus, n. sp.

This species is not closely related to any species known to me, although there may be a remote relationship to ligator Blackman. The size, scalelike elytral setae, armed anterior margin of the female pronotum, and the unexcavated female frons distinguish it.

**Female.**—Length 3.0 mm. (paratypes 2.3-3.0 mm.). 3.2 times as long as wide; color dark brown to black with white scales.

Frons convex above, somewhat flattened on lower third; surface reticulate and finely punctured above, smooth, shining on lower part of flattened area; vestiture submorse, erect, rather abundant to vertex except on shining epistomal area, short below, moderately long above. Scape broadly triangular, ornamented by a marginal fringe of long hair; club 1.6 times as long as wide, suture I reaching middle.

Pronotum 1.3 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded in front; anterior margin armed by 12 low teeth; summit in front of middle, distinct; posterior area reticulate-granulate, very minute granules indicated toward summit in median area; vestiture short, of minute hair and slender scales.

Elytra 2.9 times as long as wide, 1.6 times as long as pronotum; sides straight and parallel on basal three-fourths, rather narrowly mucronate behind; striae not impressed, the punctures minute; interstriae about four times as wide as striae, undulating slightly and with numerous indefinite points, the punctures fine. Declivity steep, convex, confined to posterior fourth; stria and interstria puncrures of equal size, close, confused, rows of minute granules on all interstria except 1; apex obesely mucronate. Vestiture consisting of minute stria hair and erect scales; scales on disc in interstria rows, more abundant and confused on declivity, each scale three to four times as long as wide; base of declivity also with several pointed bristles longer than scales, sides with some slender, long hair.

**Male.**—Similar to female except averaging slightly smaller; 2.6 times as long as wide; frons more strongly convex, not flattened below, surface with many rounded granules; scape less strongly expanded, the tuft of hair smaller; teeth on anterior margin of pronotum larger; elytral scales shorter, broader, mostly twice as long as wide, the bristles and interstria hair also scalelike and slightly larger than other scales.

**Type Locality.**—Cerro Punta, Chiriqui, Panama.

**Type Material.**—The female holotype, male allotype, and 50 paratypes were collected at the type locality on December 19, 1963 and January 11, 1964, 1.800 m., No. 315, 371, 387, 301 by S. L. Wood, from branches of Inga sp.

The holotype, allotype, and paratypes are in my collection.

**Micracis lignicolus, n. sp.**

This species is closely related to ligator Blackman, but it is distinguished by the less strongly elevated interstriae 9 at base of male declivity, and by the less strongly tuberculate interstriae at margin of declivity, by the slightly elevated, subtrunate, male declival interstriae 3 on basal third, by the different arrangement of setae on the female frons and scape, and by the narrower interstrial scales in both sexes.

**Male.**—Length 2.8 mm. (paratypes 2.5-3.3 mm.). 2.8 times as long as wide; color reddish brown.

Frons convex above, transversely impressed on lower half, epistomal margin slightly elevated; surface reticulate-granulate, with sparse, smooth granules on convex area; vestiture sparse, limited to lateral areas. Scape about twice as long as pedicel, distal width equal to length, bearing a small tuft of long hair; club 1.8 times as long as wide, suture 1 extending three-fifths of club length from base.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on basal half, weakly constricted just in front of middle, anterior margin rather broadly rounded and armed by 12 teeth; summit at middle, broad, posterior areas reticulate-granulate, the punctures fine, inconspicuous, some minute granulate; vestiture consisting of minute hair and slender scales.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; sides straight and parallel on basal three-fourths, narrowly rounded behind; striae moderately impressed on posterior third of disc, the punctured rather coarse and deep; interstriae as wide as striae, shining, somewhat irregular, the punctures indurate, rather fine. Declivity rather abrupt, convex, steep; striae not impressed, the punctures smaller and squamiforous; interstriae 1.8 each with one or two rounded nodules at base of declivity as in ligator, 9 weakly elevated but ending just behind base of declivity, 3 bearing a row of about six pointed tubercles on upper two-thirds, 5 bearing two similar tubercles near base; apex extended slightly but terminated by ascending costal margins that form a pseudo-emargination; interstria puncrures coarse, two-thirds as large as those of striae, squamiforous. Vestiture consisting of minute stria hair and interstria rows of slender, erect scales on disc; on declivity striae setae and some interstriae form moderately short scales each about four times as long as wide, other erect, interstria scales in rows, much longer at declival base, some more than twice as long as ground scales.

**Female.**—Similar to male except 3.2 times as long as wide; frons convex to epistoma, median half glabrous, devoid of granules; scape triangularly extended, bearing a much larger tuft of hair, but shorter than in ligator; striae not impressed toward declivity; declivity devoid of tubercles or nodules, 3 weakly convex; vestiture less dense on declivity, the scales more slender, not longer than on disc.

**Type Locality.**—Cerro Peña Blanca, Honduras.

**Type Material.**—The male holotype, female allotype, and 13 paratypes were taken at the type locality on April 23, 1964, 2.000 m., No. 529, in Miconia schlechtendalii, by S. L. Wood; 23 paratypes bear identical data except lot 533 taken from branches of Quercus williamsi; four paratypes were from Zamarano, Morazan Honduras, April 18, 1964, 700 m., No. 539, Quercus sapotefolia, S. L. Wood; 15 paratypes were from Volcan de Agua, 1.000 m., No. 598, from an unidentified broken branch, by S. L. Wood.

The holotype, allotype, and paratypes are in my collection.
**Micracis detentus**, n. sp.

This species is very closely related to *carinulus* Wood, described above, but it may be distinguished by the larger size, by the larger granules behind the pronotal summit, by the more deeply impressed female frons with a more prominent median elevation below, and by the coarser interstrial bristles on the declivity.

Female.—Length 2.2 mm. (paratypes 1.8-2.3 mm.). 3.2 times as long as wide; color yellowish brown.

Frons transversely, subconically impressed from epistoma to upper level of eyes, median third of epistoma moderately elevated, the smooth, impunctate, shining elevation extending about one-third of distance to upper level of eyes; remaining surface reticulate-granulate, the punctures minute, obscure; vestiture of minute subplumose hair, becoming longer toward upper margin of impression. Scape narrowly triangular, ornamented by a tuft of long hair; club 1.7 times as long as wide, suture 1 extending slightly beyond middle.

Pronotum 1.3 times as long as wide; sides straight and parallel on basal three-fourths, acuminate behind; striae not impressed, the punctures small, distinct; interstriae at least twice as wide as striae, with lines and points, the punctures inconspicuous, very fine. Declivity steep, convex, confined to posterior fourth; minutely granulate, striae deeper but somewhat obscure; interstrial punctures replaced by fine granules; apex rather strongly acuminate. Vestiture consisting of very fine short hair and rows of erect, interstrial bristles, slightly longer and coarser on declivity; each bristle on declivity slightly longer than distance between rows.

Male.—Similar to female except 27 times as long as wide; frons convex above, a moderate transverse impression on lower half, the median elevation obsolete; scape not as wide as long, bearing a small tuft of shorter hair; anterior margin of pronotum armed by eight teeth; declival vestiture slightly coarser.

Type Locality.—Twenty-four km. south of Mazamitla, Jalisco, Mexico.

*Type Material.*—The male holotype, female allotype, and five paratypes were collected at the type locality on June 22, 1965, 2,500 m., No. 91, by S. L. Wood, from branches of a leguminosae tree; 11 paratypes were taken 8 km. south of Atenequeque, Jalisco, Mexico, on June 25, 1965, 1,000 m., No. 118, by S. L. Wood, from an unidentified shrub; two paratypes were from Magurichic, Chihuahua, Mexico, July 13, 1960, blacklight, S. L. Wood.

The holotype, allotype, and paratypes are in my collection.

**Micracis unicornis**, n. sp.

This species evidently is closely related to *detentus* Wood, described above, but the male bears a large, pointed median tubercle on the epistoma, the vestiture is finer, and the clytral declivital tubercles and pronotal asperities are larger.

Male.—Length 2.1 mm. (male paratype 2.1 mm.). 2.7 times as long as wide; color reddish brown.

Frons convex above, transversely impressed on lower half; epistomal margin slightly raised, with a rather indefinite median elevation that bears a conspicuous, moderately large, pointed tubercle; surface reticulate, the punctures obscure, a few fine granules in convex area; vestiture of coarse, subplumose setae of moderate length, rather sparse. Scape twice as long and twice as wide as pedicel, bearing a small tuft of hair; club 1.5 times as long as wide, suture 1 extending slightly beyond middle of club.

Pronotum 1.05 times as long as wide; sides feebly arcuate, subparallel on basal half, rather broadly rounded in front; anterior margin armed by 12 coarse teeth; summit at middle; posterior area reticulate-granulate, with a few minute granules behind summit, the minute punctures obscure; vestiture inconspicuous, composed of stout hairlike setae.

Elytra 2.0 times as long as wide, 2.0 times as long as pronotum; sides straight and parallel on basal three-fourths, narrowly mucronate behind; striae not impressed, the punctures small, distinct; interstriae about four times as wide as striae, marked by many lines and a few points, the punctures fine, shallow. Declivity steep, convex, confined to posterior fourth; striae punctures larger and impressed; interstriae minutely granulate, the punctures replaced by fine granules. Vestiture consisting of minute striae hair and rows of erect, pointed, interstrial bristles, longer and stouter on declivity; each bristle on declivity slightly longer than distance between rows.

**Type Locality.**—Six km. west of Quiroga, Michoacan, Mexico.

Type Material.—The male holotype and one male paratype were collected at the type locality on June 17, 1965, 2,200 m., No. 72, by S. L. Wood, from a shrubby herbaceous plant.

The holotype and paratype are in my collection.

**Micracis minima**, n. sp.

The scalelike interstrial setae on the elytra and the armed anterior margin of the pronotum suggest a relationship to *evanescens* Wood, but this species is smaller and the frontal sculpture of the female is entirely different.

Female.—Length 2.3 mm. (paratypes 2.0-2.5 mm.). 3.5 times as long as wide; color medium to dark brown.

Frons broadly concave to upper level of eyes, lower third with unusual sculpture; epistomal margin slightly elevated, smooth on a narrow band on median fourth, then a slight, narrow ridge, then above this a narrow slit-like impression, rather strongly abruptly, transversely elevated above above impression on more than median half, its upper slope marked by two or three minute, transverse ridges in its gradual descent to concavity; vestiture short, sparse, inconspicuous; surface reticulate-granulate. Scape narrowly triangular, ornamented by a tuft of long hair; club 1.9 times as long as wide, widest on distal half, suture 1 extending two-thirds of club length from base.

Pronotum 1.3 times as long as wide; as in *detentus*, except some setae stout, almost scalelike.
Elytra 2.1 times as long as wide, 1.75 times as long as pronotum; outline and disc as in detentus except strial punctures rather obscure. Declivity steep, convex, confined to posterior fourth; striae weakly impressed, the punctures larger, deeper; interstrial punctures subgranulate, except reduced on 2; granules larger in some paratypes. Vestiture consisting of very fine strial hair and rows of erect interstrial scales, slightly longer on declivity; each scale on declivity as long as distance between scales, spaced more closely within each row, truncate at their apices, each about five times as long as wide.

**Male.**—Similar to female except 2.7 times as long as wide; frons convex, transversely impressed on lower half, epistoma elevated on median third, without elaborate sculpture of female; anterior margin of pronotum armed by six teeth; declival tubercles more distinct except on interstriae 2 and 3.

**Type Locality.**—Volcan de Agua, Esquina, Guatemala.

**Type Material.**—The female holotype, male allotype, and 21 paratypes were collected at the type locality on May 19, 1964, 1,000 m., No. 603, by S. L. Wood, from branches of *Celtis iguanacea*; 11 paratypes bear identical data except they are lot No. 534, from *Calliantra houstoniana*.

The holotype, allotype, and paratypes are in my collection.

*Micracis festivus*, n. sp.

Apparently the only known species allied to this one is *inimicus* Wood, described above, but it is easily distinguished by the slender elytral setae, and by the very different frontal sculpture of the female.

**Female.**—Length 2.2 mm. (paratypes 1.7-2.3 mm.), 3.4 times as long as wide; color dark brown.

Frons concavely impressed from epistoma to above upper level of eyes; epistomal margin elevated, median half with a narrow, slit-like impression just above margin and a low elevated, transverse, subcarinate ridge immediately above the slit; surface reticulate-granulate, the punctures fine, obscure; vestiture sparse, fine, short, below, longer above. Scape narrowly triangular, ornamented by a tuft of long hair; club 1.6 times as long as wide, suture 1 extending beyond middle.

Pronotum 1.2 times as long as wide; as in detentus except granules in posterior areas larger and anterior margin armed by six small teeth.

Elytra 2.1 times as long as wide, 1.8 times as long as pronotum; outline and disc as in detentus except strial punctures very slightly deeper. Declivity steep, convex, confined to posterior fourth; striae feebly impressed, the punctures deeper and slightly larger than on disc; interstriae each armed by a row of rounded granules similar to but slightly larger than in *inimicus*; apex strongly acuminate or mucronate. Vestiture consisting of fine strial hair and rows of longer interstrial bristles, slightly longer on declivity; each bristle up to one and one-half times as long as distance between rows of bristles, more closely spaced within each row.

**Male.**—Similar to female except 2.7 times as long as wide; frons as in male of *inimicus*; interstrial punctures on disc as large as those of striae, very feebly granulate; strial punctures smaller on disc and declivity, somewhat obscure on declivity; vestiture with interstrial setae on disc rather narrowly scalelike, truncate, those on declivity longer, more slender and almost pointed at their apices.

*Type Locality.**—Zamorano, Morazan, Honduras.

**Type Material.**—The female holotype, male allotype, and 16 paratypes were collected at the type locality on April 18, 1964, 700 m., No. 506, by S. L. Wood, from branches of *Celtis iguanacea*; 14 paratypes bear identical data except they are lot No. 534, from *Calliantra houstoniana*.

The holotype, allotype, and paratypes are in my collection.

*Hylocerus alternus*, n. sp.

The only species known to me that is closely related to this one is *inequalis* Wood; however, it has the male declival spines much less highly developed. The development of declival spines is similar in magnitude to *medius* Wood, but the relationship to the latter species is remote. Females of this species lack the abundant frontal vestiture of *inequalis*.

**Male.**—Length 2.5 mm. (paratypes 1.7-2.5 mm.), 2.5 times as long as wide; color very dark brown, almost black.

Frons concealed in type. In male paratype, convex and granulate above, transversely impressed and punctured below a transverse carina formed at upper level of eyes by four basally confluent tubercles; vestiture inconspicuous.

Pronotum 1.1 times as long as wide; widest near base, the sides feebly arcuate and converging very slightly on basal two-thirds then rather broadly rounded in front; anterior margin armed by about 12 coarse serrations; summit in front of middle; posterior area subshining; rather finely punctured, the posterior margin of each puncture subasperate, more coarsely sculptured toward summit. Vestiture consisting of short, inconspicuous hair.

Elytra 1.4 times as long as wide, 1.2 times as long as pronotum; sides almost straight and parallel to declival base; profile of posterior margin interrupted by projection of spines on interspaces 9 and 3 by sutural apex; striae not impressed, the punctures large, deeply impressed; interstriae narrower than striae, irregularly, sparsely punctured, each ending posteriorly at declival margin in a tubercle or spine. Declivity abrupt, very steep; upper and lateral margins armed by a row of tubercles, those on interspaces 2, 4 and 6 distinctly shorter, all tubercles abruptly decapious behind, 9 longer and projecting; declival face convex, coarsely punctated with two rather coarse tubercles on interspace 3 and about four smaller ones on middle third of 1; apex narrowly acuminate. Vestiture consisting of short, stout, bristles.

**Female.**—Similar to male except frontal carina absent, the frons more finely sculptured; anterior margin of pronotum finely serrate; elytra not abruptly decapious, without a marginal row of tubercles on declivity; each interspace bearing about three to five small tubercles on upper or lateral half of declivity.

*Type Locality.**—Twenty-one km. southeast of Liberia, Guanacaste Prov., Costa Rica.

**Type Material.**—The male holotype, female allotype, and 39 paratypes were collected at the type locality on July 10, 1966, at an elevation of
about 50 m., from a branch of an unidentified tree, by S. L. Wood.

The holotype, allotype, and paratypes are in my collection.

*Hylocurus aberrans*, n. sp.

This species is not allied to any other representative of the genus known to me. The sutures of the antennal club are more strongly procurred than in other *Hylocurus*, but less so than in *Micracis*. The posterior face of the anterior tibia is tuberculate as in *Hylocurus*; the posterior extremity of declival interspace 9 almost reaches the costal margin thereby resembling somewhat certain species of *Micracis*.

**Male.**—Length 2.2 mm., 2.6 times as long as wide; color dark reddish brown.

Frons broadly convex with a slight transverse impression just above epistomal margin; surface finely, regularly granulate. Antennal club with two procurred sutures, 1 extending two-fifths base, 2 extending four-fifths from base.

Pronotum 1.2 times as long as wide; widest on basal half, the sides feebly arcuate, rather broadly rounded in front; anterior margin armed by 16 or more serrations; summit in front of middle; posterior area reticulate, with small, subgranulate punctures of moderate abundance. Vestiture consisting of short, erect scales with a few bristles in asperate area.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel to base of declivity then slightly wider at middle of declivity; posterior outline interrupted by declival spines on interspaces 7, 8, and 9 and by short, broad, sutural apex; striae slightly impressed, the punctures deep, coarse, much smaller toward base; interspaces half as wide as striae, the punctures on 1 moderately large, others mostly minute. Declivity abrupt, very steep, almost entirely margined by a row of tubercles or spines; tubercles at base of declivity on interspaces 1 and 2 not pointed, abruptly declivous behind, those on 2 to 8 produced into increasingly large and pointed toothlike spines, 9 similar but lower and extending nearer elytral apex than normal for this genus; apex not strongly produced, its margin subsectate, the small dentitions about half as high as apex of elevation on interspace 9; central area coarsely punctured, interspace 3 slightly elevated near center and bearing three small teeth, 1 on lower third gradually elevated to apex and finely serrate. Vestiture consisting of a few stout bristles or scales at margin and on interspaces 1 and 3.

**Female.**—Similar to male except frons less strongly convex, finely punctured, ornamented by stout, short, rather sparse, setae; scape flattened and bearing a tuft of long, coarse setae; anterior margin of pronotum almost unarmed; elytra more finely sculptured, the declivity convex, without marginal ring of tubercles, the striae regularly punctured, odd numbered interspaces bearing several rounded granules; rows of broad scales on upper half of all declival interspaces.

**Type Locality.**—Dominical, Puntarenas Prov., Costa Rica.

**Type Material.**—The male holotype and female allotype were taken from the same tunnel at the type locality on December 9, 1963, at sea level, by S. L. Wood, from a small branch of a recently cut unidentified tree.

The holotype and allotype are in my collection.

*Hylocurus incomptus*, n. sp.

Fig. 3

This species is allied to *feminaeus* Wood, but it is readily distinguished by absence of sexual dimorphism on the frons, by the much more finely sculptured elytral disc and declivity, and by the steeper elytral declivity.

**Male.**—Length 2.3 mm. (paratypes 1.9-2.5 mm.), 2.6 times as long as wide; color black.

Frons moderately convex, the epistomal margin slightly elevated; a conspicuous, transverse carina occupying median half at upper level of eyes; surface coarsely reticulate, the sparse punctures minute; vestiture inconspicuous except on epistomal margin. Eye smaller than related species.

Pronotum 1.2 times as long as wide; widest at base, sides almost straight, converging anteriorly slightly on posterior two-thirds, broadly rounded in front; anterior margin subsectate; sculpture as in *feminaeus* with tubercles behind summit finer, becoming obsolete at base; vestiture inconspicuous, hair-like.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel on basal two-thirds, rather abruptly rounded behind, median fourth extending into a rather well-developed micro; striae not impressed, the punctures fine, shallow but distinct; interspaces half as wide as striae, marked by irregular lines, almost flat, the punctures minute, widely separated, becoming finely granulate on posterior fourth. Declivity convex, very steep; striae barely obscure; interspaces 3 weakly, 9 moderately elevated, 1 feebly raised and terminating apically in micro; all interspaces with a row of tubercles on upper third, minute on 2, rather coarse on 3 and last tubercle on 9, those on 3 extend to middle, on 1 two or three minute granules scattered on lower half. Vestiture hair-like, consisting of rows of short strial, and slightly longer interstriae setae on declivity.

**Female.**—Similar to male except evidently very slightly more finely sculptured; declival vestiture longer and more abundant.

**Type Locality.**—Volcan de Agua, Esquintla, Guatemala.

**Type Material.**—The male holotype, female allotype, and 63 paratypes were collected at the
Phloeocleptus plagatus, n. sp.

This species is closely allied to obscurus Wood, but may be distinguished by the much larger size, by the transverse impression of the lower frons and presence of a low median elevation above, by the absence of teeth on the anterior margin of the male pronotum, and by the somewhat more strongly elevated declivital interstriae 9.

Male.—Length 1.5 mm. (paratypes 1.4-1.8 mm.), 1.4 times as long as wide; color very dark brown, almost black in mature specimens.

Frons convex above, a moderate, transverse impression at level of antennal insertion; a short, longitudinal, median carina at upper level of eyes; surface smooth and shining at center below, becoming coarsely reticulate elsewhere, finely punctured toward smooth area, a few fine granules laterally and above; vestiture inconspicuous except near epistoma. Antennal scape short, about two and one-half times as long as wide, bearing a small tuft of hair; club small, two straight sutures indicated by setae only at lateral margins.

Pronotum 1.0 times as long as wide; sides almost straight on posterior half, converging to a feeble constriction just anterior to middle, rather broadly rounded on the unarticulated anterior margin; anterior slope asperate to summit, summit at middle; posterior area rather coarsely reticulate, with small, isolated granules decreasing in abundance toward basal margin, granules replaced by minute punctures in lateral areas. Vestiture moderately abundant, consisting of stout hairlike setae, longer in median area behind summit.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, subacutely mucronate behind; striae feebly developed, the punctures of moderate size and depth; interstriae shining, as wide as striae, the punctures fine, uniseriate. Derivility convex, steep; striae punctures reduced, obscured by subgranulate reticulation of entire declivital surface; interstriae each armed on upper half by a series of small tubercles. 1 and 3 feebly elevated, 9 more strongly raised and subcarinate on basal half; apex gradually extended toward poorly developed micro. Vestiture on disc and declivity consisting of fine, erect striae, and slightly longer, moderately stout interstrial bristles; more conspicuous on declivity.

Female.—Similar to male except antennal scape triangular and bearing a larger tuft of hair; elytral vestiture finer and somewhat shorter.

Type Locality.—Seven km. west of Tepic, Nayarit, Mexico.

Type Material.—The male holotype, female allotype, and 35 paratypes were collected at the type locality on July 13, 1965, about 1,000 m., No. 240, by S. L. Wood, from cut branches of a roadside shade tree. The tunnels were in the phloem and were similar to those of caudatus Wood.

The holotype, allotype, and paratypes are in my collection.

Phloeocleptus nanulus, n. sp.

This species is allied to plagatus Wood, described above, but it is easily distinguished
by the uniformly convex frons, by the armed anterior margin of the pronotum in both sexes, by the interstrial granules on the male disc, by the greater development of tubercles at the base of the elytral declivity and by the more strongly elevated interstriae 9.

**Male.**—Length 1.5 mm. (paratype 1.6 mm.) about 2.5 times as long as wide; color almost black.

Frons convex except epistomal margin weakly elevated; surface subreticulate, with small isolated granules except almost smooth in median epistomal area; vestiture inconspicuous. Antennal scape short, about twice as long as wide, bearing a small tuft of hair.

Pronotum 1.0 times as long as wide; outline as in *plagiatius* but anterior margin armed by four teeth, the median pair larger; sculpture as in *plagiatius*, vestiture coarser.

Elytra about 1.6 times as long as wide (elytra spread slightly), 1.6 times as long as pronotum; outline as in *plagiatius* except a small tuft of hair; striae perhaps feebly impressed, the punctures rather small, deep, larger posteriorly; interstriae almost as wide as striae, the punctures finely granulate (sub-vulcanate), the granules slightly larger near declivity. Declivity steep, convex; as in *plagiatius* except all tubercles slightly larger particularly those at base of declivity in lateral areas; interstriae 9 much more strongly elevated. Interstrial bristles on declivity longer and coarser than in *plagiatius*.

**Female.**—Similar to male except antennal scape longer, wider, and bearing a larger tuft of hair; anterior margin of pronotum armed by two small teeth; discal interstriae not granulate; lateral declival tubercles smaller, interstriae 9 not as strongly elevated; declival vestiture not as coarse.

**Type Locality.**—Seven km. west of Tepic, Nayarit, Mexico.

**Type Material.**—The male holotype, female allotype, and one female paratype were collected at the type locality on June 13, 1965, about 1,000 m., No. 240, by S. L. Wood, in series with *plagiatius* which was described above.

The holotype, allotype, and paratype are in my collection.

**Phloeoeleptus parvus**, n. sp.

This species is more closely allied to *plagiatius*, described above, than to others in the genus, but it is easily distinguished by the more slender antennal scape, by the presence of several rather large punctures on the base of the pronotum, and by the reduced number of tubercles on the elytral declivity.

**Male.**—Length 1.3 mm., 2.6 times as long as wide; color dark brown (probably not fully mature).

Frons not visible. Scape little if any wider than pedicel, about three times as long as wide.

Pronotum 1.16 times as long as wide; widest behind middle, sides feebly arcuate, almost straight and parallel on basal two-thirds, broadly rounded in front; anterior margin unarmed; summit in front of middle; posterior area reticulate, a few small, isolated granules near summit, several moderately large, deep punctures toward basal margin and in entire lateral area; vestiture fine, largely abraded.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; outline and disc as in *plagiatius*. Declivity steep, convex, shinning to apex; striae punctures slightly confused; interstriae 1 and 2 unarmed, 2 greatly narrowed near middle, 3 armed by a tubercle at middle and another at junction with 7. 7 also bearing a small tubercle at declival base, 9 more strongly elevated than in *plagiatius*. Vestiture confined to declivity, consisting of very short strial and moderately long, stout, interstrial bristles.

**Type Locality.**—Los Corchos, Nayarit, Mexico.

**Type Material.**—The male holotype was collected 2 km. south of highway 15 on the Los Corchos road on July 10, 1965, No. 206, by S. L. Wood, from a broken branch of an unidentified tree.

The holotype is in my collection.
INFORMATION FOR CONTRIBUTORS

Contributions to the Science Bulletin should be primarily monographic in nature. For the most part only manuscripts of approximately forty or more typewritten pages will be accepted.

Papers will be published approximately in the order that they are received, pending availability of funds. Authors must arrange for financing their publications, except that the University Press and the library of Brigham Young University will share the publication cost proportionately to their needs for copies of the issue printed.

In the preparation of manuscripts, authors are requested to follow the Style Manual for Biological Journals, American Institute of Biological Sciences, 2000 P Street, N.W., Washington, D.C., 20006. Manuscripts must be typed on one side of the paper only, double-spaced with ample margins. Footnotes should be avoided.

To facilitate review by referees, send to the editor the original manuscript and one carbon copy, together with the illustrations. Copies of the original illustrations may be submitted, but should be of quality equal to the originals.

Illustrations should be referred to as figures except for materials requiring inserts of special paper, which may be called plates. Illustrations should be so designed as to fit when reduced to a one-column or full-page width. Special care must be taken to allow for proper reduction in lettering (i.e., a 50% reduction of the size means also a 50% reduction in the lettering). Photographs should be of a glossy finish, unblurred, and showing sharp contrast. Line drawings should be made with black ink on heavy white drawing paper, blue tracing cloth, or blue-ruled coordinate paper. Use the same abbreviations on line drawings as in text. Line drawings must be equivalent to a professional draftsman's work. Original drawings are preferable to photographs, even if they are large. Illustrations (line drawings or photographs) should be numbered consecutively throughout the paper, and the approximate place of insertion should be indicated in the margins of the manuscript pages. Captions for illustrations should be assembled on a separate sheet, and each plate of figures must have its corresponding figure number pencilled lightly on the back. Illustrations and cuts will be destroyed unless their return is requested when proof is returned to the editor.

A table title should be a short, concise statement of what the table purports to show, and should not include information necessary to the interpretation of the table. Every column in the table should carry a head identifying the data in that column; the measure in which the data are given should be indicated at the head of each column. Tables should not be used when the same information can be given in a few lines of text, and should not duplicate information in text, graphs, or charts. Symbols (asterisk, dagger, etc.) should be used to indicate footnotes to tables, with footnotes on the same page as the table.

An abstract of less than four percent of the length of the paper should be prepared. This summary should be understandable without reference to the body of the manuscript. The abstract must be on sheets separate from the manuscript.

Proof should be corrected immediately on receipt and returned to the editor. Authors should leave forwarding addresses if they move from the address sent with the manuscript.

Reprints should be ordered when the proof is returned.

Address all manuscripts to Wilmer W. Tanner, Department of Zoology and Entomology, Brigham Young University, Provo, Utah.
