INTRODUCTION

- Many individuals diagnosed with ASD experience severe and debilitating symptoms of anxiety (Lopata et al., 2010).
- Characterization of both shared and distinct neural mechanisms in autism and anxiety may give insight into the developmental course of autism in the brain as well as improve intervention techniques (Amaral et al., 2008).
- Previous work in our lab (South, Dana, White, & Crowley, 2011; South, Larson, White, Dana, & Crowley, under review) has shown that internal emotional states do not match external behavior in ASD samples.

- We have adapted an ecologically-valid procedure studying emotion regulation in nonhuman primates (Kalnin, 2003) that we call the Intruder Paradigm for Humans (IPH).
- Five distinct phases occur while participant attends to a computerized cognitive task (See Figure 2).

METHODS

Measures
- Disposable electrodes are used to collect skin conductance response for the duration of the experiment using BioPac MP150.
- SCreen for Anxiety RelatEd Disorders—Parent Report Version (SCARED; Birmaher et al., 1997)

RESULTS

ASD group more worried in everyday life (see SCARED) and shows significant hyperactivity in motor movements. Internal SCR under-responsiveness during the IPH may suggest disconnect in brain between internal states and external behavior.

- Hypothesize that ASD are not aware of how to match their internal states with appropriate responses. There is not a total lack of understanding: no statistically significant interactions means ASD are aroused when appropriate and respond with the same pattern as TYP. May contribute to ASD children being a step behind in social situations and other cognitively demanding tasks.

CONCLUSIONS AND FUTURE DIRECTIONS

- Working with colleagues in England to build a cognitive model of anxiety in autism – what is it like to experience anxiety when you already have autism? Not understanding the world likely leads to lots of worry about the world.
- Pursuing studies of particular genotypes that link anxiety and autism in this sample; and cognitive models for representing ones’ own internal state versus monitoring others.

ACKNOWLEDGEMENTS

Thanks to participants and their families. Supported by BYU ORCA mentoring grants to T.N. and M.C.; also a BYU Mentored Environment Grant to M.S. and College of Family, Home and Social Sciences Research Awards to M.S.
